compute decompression schedules for a closed circuit underwater breathing apparatus which maintains a constant 0.7 ATA PO<sub>2</sub> in a helium diluent. The 47 test dives were all single depth dives up to 300 FSW deep with total dive times approaching 4 hours. The first three phases of testing resulted in a computer algorithm which appeared initially safe but which subsequently

produced an unacceptably high incidence of decompression sickness (DCS) on a later dive series. Investigation of this high incidence of DCS on later dives lead to the identification of a workup phenomenon which showed that previous HeO2 diving will significantly reduce individual susceptibility to DCS. Further testing resulted in a computer algorithm which would compute safe decompression schedules for divers who are not worked up. The overall raw incidence of DCS for the entire dive series was 3.73% with 37% of all symptoms being Type 2. The overall incidence of DCS was 3% lower than that found during testing of a similar computer algorithm using a constant 0.7 ATA PO2 and a nitrogen diluent but the proportion of Type 2 DCS was higher using a helium diluent than when using a nitrogen diluent. Complete details of the computer algorithm, all decompression schedules tested, and complete sets of the final decompression tables are given in the 8 appendices to this report. Complete clinical descriptions of all cases of DCS\as well as treatment results are given. The pertinence of the final decompression model to current HeO2 bounce and saturation diving is also discussed.

#### ABSTRACT

A total of 1582 man dives were done to test a computer algorithm used to compute decompression schedules for a closed circuit underwater breathing apparatus which maintains a constant 0.7 ATA PO2 in a helium diluent. test dives were all single depth dives up to 300 FSW deep with total dive times approaching 4 hours. The first three phases of testing resulted in a computer algorithm which appeared initially safe but which subsequently produced an unacceptably high incidence of decompression sickness (DCS) on a later dive series. Investigation of this high incidence of DCS on later dives lead to the identification of a workup phenomenon which showed that previous HeO2 diving will significantly reduce individual susceptibility to DCS. Further testing resulted in a computer algorithm which would compute safe decompression schedules for divers who are not worked up. The overall raw incidence of DCS for the entire dive series was 3.73% with 37% of all symptoms being Type 2. The overall incidence of DCS was 3% lower than that found during testing of a similar computer algorithm using a constant 0.7 ATA PO2 and a nitrogen diluent but the proportion of Type 2 DCS was higher using a helium diluent than when using a nitrogen diluent. Complete details of the computer algorithm, all decompression schedules tested, and complete sets of the final decompression tables are given in the 8 appendices to this report. Complete clinical descriptions of all cases of DCS as well as treatment results are given. The pertinence of the final decompression model to current HeO2 bounce and saturation diving is also discussed.

#### **GLOSSARY**

- Actual Dive Profile A table or graph showing the actual depth/time coordinates for an entire dive.
- Algorithm A sequence of logical steps used to obtain a mathematical result.
- Ascent Criteria A set of constraints on a decompression model which defines how ascent may be accomplished without causing decompression sickness.
- Bottom Time The elapsed time from leaving the surface until beginning ascent to the first decompression stop (or the surface if a no-decompression dive).
- Computer Program A series of instructions directing a computer how to process information to obtain the desired output. A computer program may contain one or more algorithms which perform intermediate calculations. As an example, a computer program for an Underwater Decompression Computer (UDC) may contain algorithms describing gas uptake and elimination, rules for finding the first stop and warning the diver when he is outside of the tested limits.
- Decompression Model A series of algorithms which describe how gas is taken up and given off by the body during a dive and what conditions must be met in order to avoid decompression sickness.
- Decompression Obligation The total amount of decompression stop time accrued at any time in a dive profile if ascent were begun at that instant at a specified rate.
- Decompression Profile A table or graph showing the depth-time coordinates for an entire dive including all desired stops and all obligatory decompression stops.
- Decompression Schedule A listing showing required decompression stop depths and stop times for a particular bottom depth/time dive at specified ascent and descent rates.
- Decompression Table A structured set of decompression schedules usually organized in order of increasing bottom depths and bottom times.
- Dive Profile A table or graph of depth/time coordinates for an entire dive showing all desired stops without regard to decompression obligation.

### GLOSSARY (Continued)

- EL-MK 15/16 Decompression Computer Algorithm (DCA) A computer program using the EL-MK 15/16 Decompression Model which will print out decompression profiles or tables given a dive profile.
- EL-MK 15/16 Decompression Model (DCM) The particular series of algorithms which describe the assumptions used in computing decompression profiles or tables for use with the closed circuit 0.7 ATA constant PO<sub>2</sub> underwater breathing apparatus.
- EL-MK 15/16 Real Time Algorithm (RTA) A computer program using the EL-MK 15/16 Decompression Model which will compute and update Safe Ascent Depth in real time given a continuous input of actual depth.
- MPTT -Maximum Permissible Tissue Tension. The maximum tension which can be present in any tissue at a given depth such that decompression sickness will not occur.
- No-Decompression Time (No-D Time) The maximum time which can be spent at a given depth (including descent time at a specified rate) such that ascent can be made directly to the surface at a prescribed rate.
- SAD

  -Safe Ascent Depth. The shallowest depth which could be ascended to at any tme in a dive profile without violating the ascent criteria. The SAD is used in real time decompression profile execution and is computed and displayed by the EL-MK 15/16 RTA.
- SDR -Saturation-Desaturation Ratio. The ratio of the theoretical tissue halftime used to compute gas uptake to the halftime used to compute gas elimination.
- Set Point -The PO<sub>2</sub> in a closed circuit UBA at which oxygen is added to the breathing loop.
- Theoretical Halftime Tissue A conceptual area of body tissue whose gas uptake can be described by an exponential term with a time constant K or halftime equal to ln(2)/K.

#### Development of a Computer Algorithm for Constant 0.7 ATA Oxygen Partial Pressure in Helium Diving

By: Edward D. Thalmann, CDR, MC, USN

#### INTRODUCTION

Several years ago, the Explosive Ordnance Disposal (EOD) Community undertook the development of a new Underwater Breathing Apparatus (UBA) to replace the aging MK 6 UBA. The result of this development was the MK 16 UBA which electronically controls the oxygen partial pressure ( $PO_2$ ) to a predetermined level independent of depth. Functionally, the MK 16 is almost identical to the MK 15 UBA; the main difference being that the MK 16 has a low magnetic and acoustic signature necessary for the EOD environment (1,1a). Both the MK 15 and MK 16 can use either a nitrogen or helium diluent depending on the type of diving being done. Previous studies at NEDU have described the development of a computer algorithm for computing constant 0.7 ATA  $PO_2$  decompression tables using a nitrogen diluent (3,4). This computer algorithm also served as the basis for a computer program for a small wrist-worn Underwater Decompression Computer (UDC) which would compute decompression obligation in real time for a 0.7 ATA constant  $PO_2$  in  $PO_2$  in  $PO_2$  breathing gas as a dive was being conducted (4).

The purpose of the present study was to develop a computer algorithm which could be used to compute a set of decompression tables using helium as a diluent and also be programmed into a UDC, if desired. Since the EOD mission does not require complex multiple level dives this study looked only at single depth dives (square dives). In addition, since the MK 15 and MK 16 are functionally similar and both control the  $PO_2$  in the same way (1,1a,2,2a), dives were done using the MK 15 UBA, the MK 16 not being available at the time of the study. However, the decompression algorithm developed in this study are applicable to either the MK 15 or MK 16 as long as the set point is 0.7 ATA and the appropriate diluent is used.

In addition to testing square dive decompression schedules, an emergency procedure for use in operational diving whereby a diver breathing an  ${\rm HeO_2~mix}$  on the bottom breathed air during decompression was tested. This would allow surface-supplied air SCUBA supplied via a HOOKA to be used in the event of a UBA failure during decompression.

This report is intended to be both encyclopedic and archival and as such may seem overdetailed in parts. As much information as possible was included covering all facets of the dive series. The intent was that future investigators should find any information they may need for future analysis in this report minimizing the need to consult original data sources. In addition, reasons for all changes in analysis or methods are given even if the decisions were arbitrary to minimize future conjecture.

#### **METHODS**

というのでは、これのことがある。これがある。これでは、これではないでは、これがあっているは、これのものではなっている。これできない。

#### General

All 174 divers who participated in this study were active duty Navy or Army divers, or military trained civilians. Divers from the U.S., Canadian and British military participated. The physical characteristics of all divers is given in Appendix A. One of the divers (#134) was a female. There were 5 separate dive series (Phases I, II, III, IV and V) and some subjects participated in more than one phase. Divers were all actively exercising up to the time of their participation in the study and were all in good physical condition. All divers were given thorough diving physical examinations before each dive series began and were examined immediately before and after each dive by a U.S. Navy Diving Medical Officer. Physical characteristics for all divers are found in Appendix A.

All divers were thoroughly trained in the use of the MK 15 closed-circuit constant PO, UBA and all dives were done using the MK 15 UBA with the PO, setpoint adjusted to 0.7 ATA. A complete description of the MK 15 hardware and operating characteristics is given in references (2) and (2a). With a PO2 setpoint of 0.7 ATA, the MK 15 will automatically add oxygen when the PO2 Normally, the PO2 will have a mean level between 0.7 ATA falls to 0.7 ATA. and 0.8 ATA, but could be as low as 0.6 ATA without the UBA indicating a malfunction. This PO2 range is maintained irrespective of depth. There is an alarm light that will warn a diver if his PO2 falls to 0.6 ATA. happened during dives in this study, the diver was instructed to manually add oxygen and to change to another UBA if PO2 could not be maintained automatically in the 0.6-0.8 ATA range. As long as no alarm lights indicated a low  $PO_2$ , divers were instructed to let the UBA control automatically and no attempt was made to control the  $PO_2$  at exactly 0.7 ATA. As will be seen later, this means that the tables resulting from this dive series could be used with any UBA which uses a helium diluent and which controls to a mean PO2 of 0.7 ATA (or greater) as long as it warns the diver when the PO2 falls to As will be seen, the final version of the MK 16, which is the UBA 0.6 ATA. which will be primarily used with the tables, has a set point of 0.75 ATA and warns the diver when the PO2 falls below 0.6 ATA.

The diluent used for all dives in this series was 100% helium. Operationally a  ${\rm HeO_2}$  mix will be used which would result initially in higher oxygen partial pressures immediately after compression as diluent gas is added to the breathing loop to make up volume. By using 100% helium the oxygen partial pressure during the first portion of time at depth will be lower than it will be when operational dives take place. Since a lower  ${\rm PO_2}$  is presumed to increase decompression obligation, tables were developed under conditions of maximum decompression stress with respect to oxygen partial pressure.

All dives were conducted in the 15 foot diameter by 46 foot long wet chamber of the Ocean Simulation Facility (OSF) at the Navy Experimental Diving Unit (NEDU) in Panama City, Florida. Divers were generally divided into 10 man teams. While at depth the 10 divers performed intermittent exercise at 75 watts on an electrically braked bicycle ergometer pedalling at 55-60 RPM.

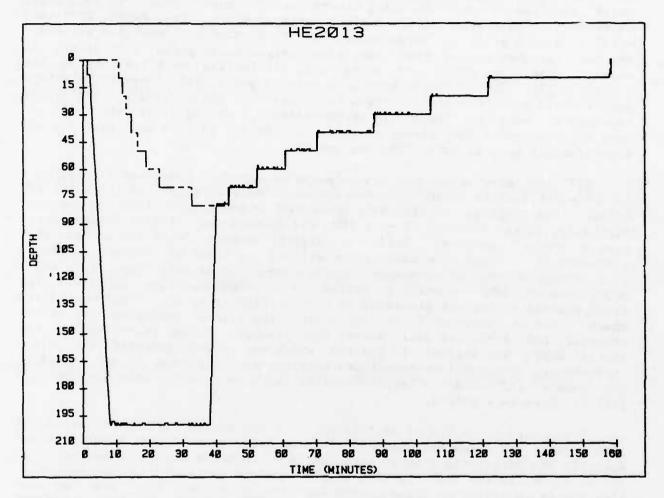

Since only 5 bicycle ergometers were available, only half the divers were actually exercising at a given time. Exercise periods lasted 6 minutes at which time the 5 non-exercising divers mounted the ergometers and began exercising. This alternating 6 minute work, 6 minute rest cycle continued until 1 minute prior to decompression at which time all exercise stopped. Previous studies showed that the mean oxygen consumption for divers in wetsuits pedalling 55-60 RPM doing this alternating work/rest cycle was approximately 1.00-1.2 l/min with a 1.6-1.8 l/min oxygen consumption during exercise and a 0.4-0.5 l/min oxygen consumption at rest (1,14)<sup>2</sup>. All divers remained at rest for the entire decompression. During dives where air was used for decompression, divers came off of the MK 15 UBAs and breathed air from standard open circuit SCUBA regulators.

All dives were done using a decompression schedule generated in real time by a Hewlett-Packard HP 1000 Series Computer using an algorithm as described below. The computer continuously monitored chamber depth from an Ashcroft Digigauge to an accuracy of + 1 FSW and updated the diver's decompression status every 2 seconds. Real time algorithms were developed as described elsewhere (5). Real time computation allowed any holds or changes in travel rate during ascent and/or descent to be taken into account thus producing a decompression schedule exactly suited to a particular dive profile. The decompression status was displayed on a video display as the shallowest depth which could be ascended to at any given time without violating the ascent criteria, the so-called Safe Ascent Depth (SAD). During decompression the divers' depth was matched to the SAD which was always computed in 10 FSW increments. The actual dive profiles were continuously recorded and stored by the computer and could be retrieved after the dive. A typical dive profile plot is shown in Figure 1.

Dives were accomplished as follows. Divers donned their UBAs outside of the chamber and breathed chamber air as they entered the water. After entering the water, all divers switched from breathing air to breathing from the MK 15 UBA at the end of a full inspiration and descended to the bottom of the wetpot in unison on signal from the Dive Supervisor, thus ensuring that computer updates regarding breathing gas changes and depth changes corresponded exactly to what the divers were doing in real time. Dive time began when the divers began breathing from the MK 15. Once at the bottom of the wetpot (a depth of 7 FSW to mid chest), all divers were instructed to remain upright with their feet just touching the floor of the wetpot. The bicycle ergometer frame heights were such that exercising and non-exercising divers were within 1 FSW depth of each other at mid chest. Thus, the assumed depth error over an entire dive was + 1 FSW between divers.

<sup>1</sup> Some dives had bottom times too short for each team member to do a full 6-min exercise run. In these cases, each team member exercised for one-half of the available bottom time.

 $<sup>^2</sup>$  NEDU Report 1-84 (4) mistakenly reported divers exercising 10 min at 50 watts. In fact, the exercise protocol for the  $\rm N_2O_2$  dives (4) was exactly the same as done in this study.

FIGURE 1. Typical Dive Profile. The actual depth is the solid line and the computer generated Safe Ascent Depth (SAD) is the broken line. HE2013 is the computer file name signifying the 13th dive of Phase II. This is an HVAL07 schedule to 200 FSW with a 120 min total decompression time. This profile was designated as a 200/30 schedule but the total decompression time actually puts it somewhere between 200/30 and 200/35. (See Appendix H).

Descent rates were 30-60 FSW/min depending on diver's ability to clear their ears. In some cases there were holds on the way down followed by intermittent ascents because of eustachian tube blockage in some divers. Since the decompression schedules were all computed in real time all these holds were taken into account in determining actual decompression obligation. Ascent rates were 60 FSW/min to 20 FSW, 40 FSW/min to 10 FSW, and 30 FSW/min from 10 FSW to the surface, these being the maximum OSF wet chamber travel rates over these depth ranges.

The wet chamber was pressurized with HeO2 only during Phase I and with air for all other phases. Occasionally, a diver would have to come off of his UBA while at depth because of a rig malfunction. A dry underwater refuge was in the wetpot and always contained an HeO2 atmosphere. The PO2 of the refuge was close to but not always exactly 0.7 ATA and contained no nitrogen. diver had to breathe refuge atmosphere for more than a few minutes he was eliminated as a test subject from that particular dive. Chamber occupants (tenders or divers withdrawn from the wetpot) always breathed an HeO2 mix with a PO2 much greater than 0.7 ATA by mask (6-10). As previously mentioned, no effort was made to regulate PO2 as long as the MK 15 was controlling the PO2 normally, that is between 0.6 and 0.8 ATA. If a diver found his PO2 outside of this range (as indicated on the MK 15 secondary display), he first adjusted the PO<sub>2</sub> manually to 0.7 ATA. If the UBA still failed to properly control the PO2, the diver was immediately given another UBA.

The only criteria used to evaluate the safety of a paticular dive profile was the occurrence of clinical decompression sickness. The determination as to whether or not a particular diver had decompression sickness was made by an experienced U.S. Navy Diving Medical Officer who evaluated both subjective and objective signs and symptoms. If, in the opinion of the examining Diving Medical Officer (based on diver history and physical examination), decompression sickness was present, then appropriate treatment was instituted. other criteria (such as ultrasonic doppler monitoring) were used to determine whether or not decompression sickness was present. Usually symptoms of decompression sickness would not manifest themselves until the diver surfaced in which case only the stricken diver was treated. In some instances symptoms occurred while still at depth and when the stricken diver could not be isolated in another chamber all the other divers on that particular dive were treated along with the stricken diver. In these cases, the asymptomatic divers were not included in the dive statistics at all while the stricken diver was counted as a case of decompression sickness. All treatments for decompression sickness were done using standard U.S. Navy Oxygen Treatment Tables unless otherwise noted.

Each of the MK 15 UBAs had a gas sample line on the CO2 absorbant canister effluent side. During rest periods divers would enter the underwater refuge and connect the UBA gas sample line to a snap fitting recepticle which piped the UBA gas sample to a mass spectrometer (MGA 1100 Perkin Elmer Co.) located outside of the chamber. This allowed periodic analysis of UBA  $0_2$ ,  $CO_2$ ,  $N_2$  and He levels.

#### Water Temperatures, Inspired Carbon Dioxide:

Water temperature was adjusted to maximize thermal stress on the diver without causing dive aborts. Temperature was set (+ 2°F) according to the

total dive time as follows: 360 min or greater, 65°F; 359-190 min, 60°F; 189-80 min, 55°F; 79-30 min, 50°F; 29 min or less, 45°F. Total dive time was estimated before the dive and in actuality may have been several minutes longer or shorter than planned depending on the number of holds during ascent. All divers wore full 1/4" neoprene wetsuits consisting of "Farmer John" trousers, jacket, hood, gloves and boots. Most divers were visibly chilled and shivering when exiting from dives. The only exception to the above temperatures was during 47 man dives done at the end of Phase I testing which were done in 71°F water.

Inspired  $\mathrm{CO}_2$  tension was not allowed to rise above 7.6 mmHg as monitored on the mass spectrometer without having the diver switch to another MK 15 UBA. The usual range of  $\mathrm{CO}_2$  tension was 0-2 mmHg with the maximum values occurring after 4-5 hours during long 250 and 300 FSW dives. UBA gas sampling was not done during Phase IV and and Phase V because experience from Phase I-III showed that inspired  $\mathrm{CO}_2$  would not rise above 2 mmHg in a normally functioning UBA during the maximum anticipated total dive time (5 hrs).

#### Decompression Model and Computer Algorithms

The object of this study was not to test decompression tables but rather to develop and test a computer algorithm which could be used to compute a set of decompression tables. In doing the testing, depths and bottom times were chosen based on UBA maximum operational depth and time limits to define the depth-bottom time domain within which the computer algorithm would compute safe decompression schedules in real time. Once this depth-time domain was defined and manned testing had verified its safety, this computer algorithm would then be used to compute a set of decompression tables for any desired depth/bottom time combination within that domain. In addition, the same computer algorithm could be used to compute decompression schedules in real time using a suitable computer and depth monitor.

The decompression model is the set of assumptions describing the assumed physiology involved in gas uptake and elimination by the body during a dive as well as the criteria which must be met to avoid decompression sickness (also called ascent criteria). The decompression model used for this study is the Exponential-Linear (EL) version of the model used in developing the computer algorithm for 0.7 ATA constant  $PO_2$  in  $N_2$  diving and is thoroughly described elsewhere (ref. 4, Appendix A). This decompression model will be referred to as the Exponential-Linear MK 15/16 Decompression Model (EL-MK 15/16 DCM). While the decompression model actually encompasses all equations and assumptions necessary for avoidance of decompression sickness (DCS), reference to the EL-MK 15/16 DCM will refer mainly to that portion of the model describing gas uptake and elimination. The other portion of the model which defines the ascent criteria are found in the various Maximum Permissible Tissue Tension (MPTT) Tables which define the maximum gas tension allowed in any of the theoretical halftime tissues at a given depth. Thus, to compute a decompression schedule the EL-MK 15/16 DCM computes tissue tensions based on the desired dive profile then computes decompression stops such that no tissue exceeds its MPTT at any depth. The intent is that by never having any tissue exceed its MPTT, decompression sickness will be avoided.

In order to actually compute decompression tables and perform man dives the decompression model must be translated into a computer algorithm (or program) which will accept input and actually calculate a decompression schedule in real time or print out a set of decompression tables. The EL-MK 15/16 DCM served as the basis for two computer algorithms. The first was the EL-MK 15/16 Decompression Computer Algorithm (EL-MK 15/16 DCA) which was a computer program designed to accept as input sets of depth time coordinates and which would print out a decompression schedule for a profile of any degree of complexity (program DMDB7) or a complete set of decompression tables (program TBLP7). Both DMDB7 and TBLP7 are input/output programs and the decompression model is contained in the EL version of the 8 subroutines used by the programs. These two programs and the associated £L versions of the subroutines have been previously documented (5) and will be referred to collectively as the EL-MK 15/16 DCA.

Using the same EL-MK 15/16 DCM, a computer program was written which would compute decompression schedules in real time. This program is known as the EL-MK 15/16 Real Time Algorithm (EL-MK 15/16 KTA) and is described elsewhere (4). In the real time version, the EL-MK 15/16 DCM updates tissue tensions every 2 sec given the current depth as monitored by a digital depth gauge. It then computes the minimum depth which could be ascended to at any instant such that no tissue exceeds its MPTT, and displays the result as the Safe Ascent Depth (SAD). In doing this study, the optional warning status used in the  $N_2O_2$  version of the EL-MK 15/16 RTA (4) was not implemented.

Both the EL-MK 15/16 DCA and RTA accepted the same set of ascent criteria in the form of MPTT Tables. The MPTT's in this study were designed specifically for a helium-oxygen breathing gas and a total of 13 different sets were used and are presented in Appendix E. These MPTT's specify the number and halftimes of the theoretical tissues to be used by the computer algorithms as well as the Saturation Desaturation Ratio (SDR). The SDR is the ratio of tissue halftimes used for computing gas uptake to that used for computing gas elimination. During computation of gas uptake (saturation) the tissue halftime as shown in the MPTT Table is used but during offgassing (desaturation) this halftime is divided by the SDR to get the desaturation Various MPTT's used 6 or 9 halftime tissues and SDR's were always halftime. These MPTT's are labeled HVAL01 through HVAL21, the "HVAL" 1.00 or less. signifying a HeO2 MPTT Table and the 2 digit number reflecting the particular version. While a total of 21 sets of MPTT's were considered, not all were tested.

In the decompression tables in Appendices F (page F-1) and G (page G-4, G-28), a table of Blood Parameters appears on the same page as the MPTT Tables. These Blood Parameters are not part of the ascent criteria but show the values for various blood gas values assumed by the decompression model, the significance of which is discussed clsewhere (4). The values of the Blood Parameters used for development of  ${\rm HeO}_2$  algorithms were the same as used in developing the  ${\rm N}_2{\rm O}_2$  algorithm and were not changed during this study.

Throughout this study only the number of halftime tissues, SDR's and individual MPTT values, as listed in Appendix E, were changed in attempting to compute safe decompression schedules. All other aspects of the decompression model remained unchanged throughout the study.

#### Compensating For Nitrogen:

In doing surface-supplied  $HeO_2$  diving the divers start out saturated on nitrogen. Once they are breathing  ${
m HeO}_2$  from the MK 15 or MK 16 closed circuit UBA the amount of nitrogen in the UBA cannot increase since none is added but it will decrease with time as gas is vented from the UBA during ascents. decompression model tested here is a single inert gas model with 6-9 halftime The tissue halftimes cannot be considered as pure helium halftimes since some tissue nitrogen will be present. In addition, the MPTT Tables used to establish the ascent criteria reflect total inert gas tension, a small fraction of which will be nitrogen. Thus, the decompression tables tested are actually tri-mix tables with the majority of the inert gas being helium and a This means that the EL-MK 15/16 DCM cannot be small fraction being nitrogen. used for computing HeO<sub>2</sub> decompression schedules under conditions vastly different (e.g. switching between  $N_2O_2$  and  $HeO_2$ ) from the closed circuit environment tested here. Appendix B goes into more detail in describing the errors generated by the single inert gas model when two inert gases are In the square dive environment, these considerations are not breathed. If this model is used for repetitive dive calculations the significant. offgassing of helium at the surface while breathing air may have to be calculated using a two inert gas model. These are considerations which must be taken into account for future testing.

#### Test Profiles

Two types of test profiles were done, no-decompression and decompression. Appendix H provides comparison of profiles for each tested MPTT modification. When doing decompression profiles divers were compressed to the desired depth at a rate of 30 to 60 FSW/min but occasionally holds occurred so mean descent rate varied considerably from dive to dive. In order to keep profiles at a given depth comparable, the actual time for leaving the bottom was determined A Hewlett Packard HP 1000 computer was by total decompression time. programmed to compute total decompression time every 2 seconds along with the Thus, every 2 seconds the Diving Officer knew exactly how many minutes of decompression would be required if ascent were begun at that instant. Before the dive, a complete set of decompression tables were calculated using the EL-MK 15/16 DCA assuming a 60 FSW ascent and descent rate. Each one of these profiles had a total decompression time associated with it. the planned schedule was 200 FSW for 30 min the divers were compressed to 200 FSW and after arrival stayed at 200 FSW until the total decompression time as calculated by the HP 1000 was the same as that in the 200 FSW for 30 min decompression table. At that instant decompression was begun and accomplished by matching diver depth with the SAD. By using this procedure the actual time at depth was adjusted to take total descent time into account such that upon leaving depth the theoretical tissue tensions for controlling tissues were the same as for the profile in the previously computed tables where a 60 FSW/min Thus, when a 200 FSW/30 min profile is referred to descent rate was assumed. in this report it means a profile where after arriving at 200 FSW divers stayed at depth until the total decompression time was the same as for a diver who left the surface and traveled to 200 FSW at exactly 60 FPM and stayed at depth for exactly 26.33 min (total bottom time equal to the 3.66 min descent

time plus 26.33 min at depth) and ascended at exactly 60 FPM during decompression. Thus, all profiles began ascent at very close to the same theoretical tissue tensions although actual times at depth may have differed by a few minutes depending on the actual descent time.

Decompression stops were in 10 FSW increments and the first stop could usually be reached at an ascent rate close to 60 FSW/min. When using the EL-MK 15/16 RTA there are no significant differences in offgassing rates at depths within 10 FSW of each other so small delays in leaving a stop or slow ascent rates between stops have no significant effect on total decompression time. At the 10 FSW stop, the chamber depth was 3 FSW with divers at the bottom of the 7 foot wetpot water column. Since it generally took 30 sec to travel this last 3 FSW, travel was begun when the HP 1000 computer showed 30 sec remaining at the 10 FSW stop. At the instant the HP 1000 showed that the divers could surface, all divers ascended to the surface, left the wetpot, and immediately began breathing chamber air. This procedure, when followed, always had the divers within 1 FSW of the surface when the HP 1000 showed that they could ascend to the surface. Once the chamber was at the surface, divers swam to the ladder and exited the chamber always breathing air.

#### No-Decompression Dives:

The EL-MK 15/16 RTA used to compute the SAD would also calculate the time remaining until the SAD would increase from 0 to 10 FSW. As long as the SAD was 0, the divers were within no-decompression limits. Thus, at any given depth no-decompression time was the time remaining before the SAD increased from 0 to 10 FSW and the remaining time until this happened was computed and displayed every 2 seconds. Programming constraints in the real time environment dictated that this time be computed assuming instantaneous ascent. Thus, once at depth, the no-decompression time was computed by calculating the shortest time it would take any tissue to saturate from its current value to its surfacing tension (10 FSW row of the appropriate MPTT Table). Since some tissue offgassing would always occur during ascent, this instantaneous no-decompression time would always have a shorter bottom time than a no-decompression time calculated taking a finite ascent rate into account.

During Phase I testing, decompression was begun when the SAD increased from 0 to 10 FSW and generally the SAD would decrease back to 0 FSW before the divers actually reached 10 FSW. Fig. 2 shows a depth profile for a 200 FSW dive with the SAD plotted as well. Decompression was started when the SAD increased from 0 to 10 FSW. If the 60 FSW/min ascent rate could have been maintained all the way to the surface, the divers would have arrived at the surface about 35 sec afer the SAD dropped back to 0. Because of slowed actual ascent shallow, the divers arrived at the surface almost 2 minutes after the SAD decreased to 0. Ideally, one would like to extend the time at depth so that during ascent the SAD decreases from 10 to 0 FSW the instant the divers reached 10 FSW. In Phase II the procedure for doing the 200 FSW nodecompression dive was modified to more closely approximate this ideal situation as shown in Fig. 3. Ascent from 200 FSW was not begun until the HP 1000 showed that a 1 minute stop at 10 FSW was necessary. During ascent the SAD actually increased to 20 FSW and upon arrival at 10 FSW a stop was taken

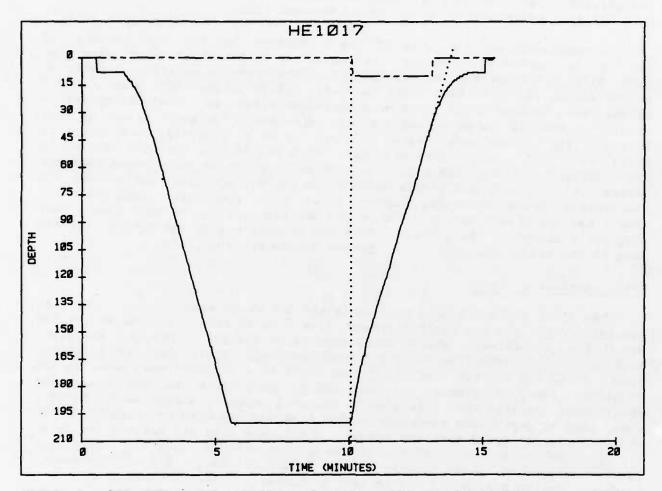

FIGURE 2. 200 FSW No-Decompression Profile. Same format as Figure 1. This is an HVALO3 schedule. After arrival at 200 FSW, ascent was begun at the time the SAD increased from 0 FSW to 10 FSW. A 60 FSW/min ascent rate was maintained until 30 FSW at which point it began to fall off. The divers were surfaced almost 2 min past the time the SAD returned to 0 FSW. Even if the ascent rate could have been maintained all the way to the surface (dotted line extrapolation), the divers would have surfaced about 35 seconds after the SAD decreased to 0 FSW.

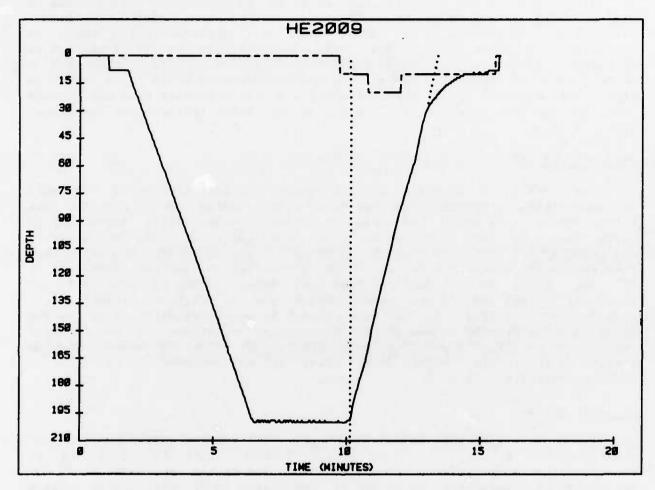

FIGURE 3. 200 FSW Minimal Decompression Profile. Same format as Fig. 1. In this HVAL06 schedule, ascent was begun with the HP 1000 computer showing about a 2 min stop at 10 FSW. Upon arrival at 10 FSW, there was a 1.2 min stop after which the divers were surfaced at the moment the SAD decreased to 0 FSW. This method allowed the decompression model to be followed exactly while getting as close to actual no-decompression times as possible.

until the SAD decreased to 0. This usually was less than 1 minute. The divers now arrived at the surface only 10 sec after the SAD decreased to 0. This dive was counted as a no-decompression dive but was actually a minimal decompression dive.

Since most of the no-decompression dives were done as illustrated in Fig. 2, these divers actually would have received some additional decompression during ascent. This means that the no-decompression limits as computed using these MPTT values would theoretically be too long. This potential problem was obviated because when MPTT values were adjusted to compute safe decompression dives, the no-decompression times were shortened (Table H-1, Appendix H). This shortening was always greater than the excess decompression time taken during the no-decompression testing done as illustrated in Fig. 2.

#### Deep Stop Dives:

The EL-MK 15/16 DCM predicted that taking the last stop at 20 FSW could be done without lengthening decompression time. Being able to take the last decompression stop at 20 FSW would be useful operationally, especially in In order to determine if the EL-MK 15/16 DCM would follow theory and actually allow the last stop to be taken at 20 FSW, 3 sets of dives were done where the divers remained at 20 FSW even after the SAD had decreased to 10 FSW. Since the EL-MK 15/16 RTA uses actual depth to compute tissue tensions, divers can always remain below the SAD without violating the decompression criteria. In this case, ascent from a diver depth of 20 FSW was begun when the HP 1000 showed about 30 sec remaining before the SAD deceased from 10 to 0 FSW. The divers were decompressed directly from 20 FSW and arrived at the surface within 30 sec after SAD had decreased to 0. shown graphically in Fig. 4.

#### HeO2/Air Dives:

In these dives the divers switched from breathing the MK 15  $\rm HeO_2$  breathing mix to air from open circuit SCUBA regulators at the first decompression stop shallower than 80 FSW. The switch was made at 80 FSW because at this depth the  $\rm PO_2$  on air is very close to 0.7 ATA. Thus, during all decompression shallower than 80 FSW, the diver would be breathing a  $\rm PO_2$  less than 0.7 ATA. Also, by not breathing air deeper than 80 FSW, any additional benefit from breathing a  $\rm PO_2$  above 0.7 ATA was eliminated. The divers decompressed according to the SAD as computed by the HP 1000 as if they were still breathing an  $\rm HeO_2$  mix from the MK 15. Thus, the decompression profile was not changed by breathing air. Instead, the intent was to see if the divers could safely decompress on an  $\rm HeO_2$  profile breathing air.

#### RESULTS

The dive series described in this report consisted of 5 phases. Phase I occurred from 21 January through 17 February 1982; Phase II from 29 March through 28 April 1982; Phase III from 5 August through 2 September 1982; Phase IV from 8 September through 21 September 1983; and Phase V from 9 April through 27 April 1984. Phases I-III were initially conceived as testing of square dive schedules to 300 FSW and Phase IV was initially designed to test

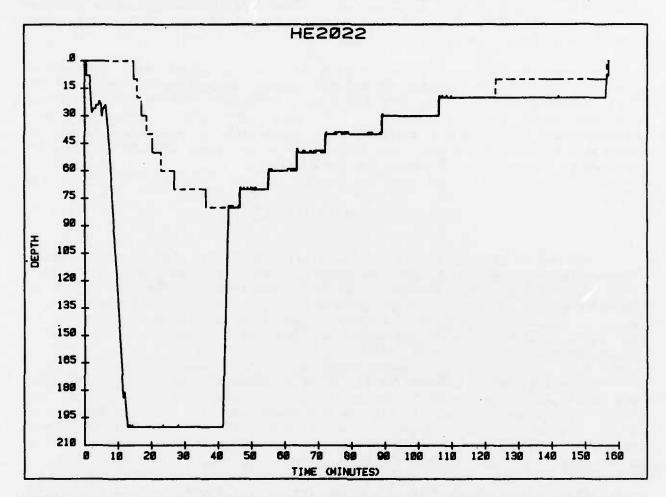

FIGURE 4. Deep Stop Profile. This HVALO7 Profile is almost the same profile as Fig. 1 but the total decompression time was 115 min due to a slightly longer bottom time. During decompression the actual depth was matched to the SAD until a depth of 20 FSW was reached where the divers remained at 20 FSW even after the SAD had decreased to 10 FSW. When the SAD finally decreased to 0 FSW, the divers were brought directly to the surface. Taking the last stop at 20 FSW did not lengthen the total decompression time over what it would have been if actual depth had been matched to the SAD all the way to the surface.

the emergency decompression procedure breathing air which were described earlier. An unexpectedly high incidence of decompression sickness (DCS) during Phase IV testing caused that protocol to be changed to investigate the reasons for this DCS. Phase V was then designed to test schedules as revised based on Phase IV testing and also to test the emergency air decompression procedure using the  $\rm HeO_2/Air\ dives.$ 

A total of 1582 man dives resulting in 59 cases of DCS were done using some 48 test profiles. Table 1 summarizes the depth/bottom time combinations for Profiles 1-44 using only  ${\rm HeO}_2$  and Table 2 Profiles 45-47 using air during decompression. (Note there is a profile 35 and 35a). Times for no-decompression dives are not designated for each HVAL and are given in square brackets. In the body of the table the number of man dives done is followed by the number of cases of DCS after the slash mark.

#### Phases I-III Testing (HVAL13 Tables)

Detailed results of Phases I-III are given in Tables 3 through 5. Table 3 shows the results of all no-decompression dives done during Phase I and the first part of Phase II. The particular no-decompression bottom time tested is shown in Square brackets. All dives were done in cold water at temperatures given in the METHODS section except for 18 man dives at 60 FSW for 147 min, 19 man dives at 100 FSW for 34 min and 10 man dives at 120 FSW for 20 min; these dives being conducted in warm (71°F) water.

Table 4 gives the results of all Phase II decompression dives. Phase II was designed to produce an algorithm which could compute tables down to 200 FSW. It was during Phase II that the decompression dives with the last stop at 20 FSW were tested. These 28 man dives were all 200 FSW for 30 min and have their bottom times noted as 30D, and no cases of DCS occurred during these deep stop dives.

After completion of Phase II, Phase III was instituted to fill in gaps in decompression profiles from Phase II. Results of Phase III are given in Table 5. The goal after completing the first three phases was to have tested a no-decompression profile, one with the maximum permissible bottom time and one intermediate bottom time profile at 20 FSW increments from 60 to 200 FSW. Maximum bottom times were chosen to give a total dive time of 3-4 hrs. The final portion of Phase III was designed to extend the depth range to 300 FSW. During these deep dive tests, only two depths were used, 250 and 300 FSW and maximum bottom times were chosen to give a 3-4 hr total decompression time. No-decompression diving to these depths was judged to be impractical so a 10 min bottom time was chosen as the shortest bottom time to be tested.

Descriptions of all cases of decompression sickness for Phases I-III are given in Appendix C, Tables C-1 through C-3. The letter codes in the body of Tables 3 through 5 key the dives to the descriptions in Appendix C. Appendix D Tables D-1 through D-3, show the individual subject diving intensities for Phases I-III. (Note that subject numbers are the same for all five phases). On each specified date the profile number (from Table 1 and 2) of the profile

Letters Key DCS to Descriptions in Appendix C.

dove by each subject is given. All cases of DCS are noted as well as dives which were not completed by the subject (usually because of ear squeezes or equipment malfunction). Note in Table D-1 that profile 17N was a 120 FSW for 19 min dive done using a nitrogen diluent. These dives are only reported in this table for completeness and are not included anywhere else, but were previously reported with the  $N_2O_2$  algorithm test results (4).

Based on the results of Phases I-III a comprehensive set of decompression tables using HVAL13 were generated by the program TBLP7 (5) and are given in Appendix F. Table 6 summarizes the dives from Table 1 which had shorter decompression times and/or stop depth/time distributions significantly different from the HVAL13 schedules established during Phases I-III and therefore fell outside of the HVAL13 limits. Table 6a shows the dives which did fall within these limits. Based on these results, the expected incidence of DCS was 4.0% for no-decompression dives, 3.4% for decompression dives and 3.9% overall (Table 6a), assuming a binomial distribution at the 95% confidence level. It was thought initially that these would be the final set of  ${\rm HeO}_2$  Decompression Tables.

#### Phase IV Testing

Phase IV was instituted to test an emergency procedure being developed for use with the  $0.7~\mathrm{ATA}$  constant  $\mathrm{PO}_2$  in He profiles in the operational environment. This procedure was designed to address the problem of a closed circuit UBA failure at depth where the diver was no longer within no-The procedure called for lowering to the diver an open decompression limits. circuit SCUBA regulator on a long hose supplied with air from SCUBA bottles in a surface support craft. The diver would then breathe air all the way to the surface following the appropriate 0.7 ATA constant PO2 in He decompression Theoretically this should cause no problem from a schedule to the surface. decompression standpoint since when breathing air inspired helium tension would be zero and helium offgassing should increase. Since the diver would start decompressing right away in the event of a UBA failure he would not incur any significant nitrogen uptake from breathing the air, which might increase his decompression obligation. In testing this procedure air was not breathed until the diver was shallower than 80 FSW which meant the  $PO_2$ breathing air was always less than 0.7 ATA. This precluded against any possible benefit from breathing an increased oxygen tension at depth.

In training for Phase IV as initially planned, a series of 120 FSW for 40 min  $\text{He0}_2$  dives were planned, to be done in exactly the same manner as Phase II and III dives. During Phase III, 40 DCS-free man dives had been done on this schedule using HVAL12 which generates the same decompression schedule as HVAL13 (Appendix H). Two groups of divers, A and B, were to participate in the study. Group A dove first and the 7 cases of DCS which resulted after only 17 man dives (Table 7) caused cancelling of Group B dives and reconsideration of the proposed protocol.

Given the previous lack of DCS on the 120 FSW for 40 min schedule, the only explanation that seemed plausible to account for the unexpectedly high DCS incidence in the Phase IV Group A divers was that the diving intensity from Phases I-III conferred an increased tolerance to DCS on the divers in those phases thus resulting in the low DCS incidence when they dove the 120/40 schedule. This phenomenon has been previously described in both tunnel workers

and divers and a good review of applicable literature is given by both Hempleman (21) and Vann (19). Working on the premise that some sort of "work-up" phenomenon existed it was decided to forego testing of the emergency air breathing procedure during Phase IV and investigate this postulated phenomenon. Two work-up scheules were devised. The 80 FSW no-decompression work-up dive had a 50 min bottom time which was 17 min less than the 67 min no-decompression limit tested in Phase I. This was considered a particularly non-stressful dive. The next work-up dive was 100 FSW no-decompression dive for 30 min (3 min less than the HVAL13 no-decompression limit) which was considered moderately stressful. Based on analysis of dives from Phases I-III (as will be discussed) a minimum elapsed time of 48 hrs between work-up dives was established.

The results of Phase IV are given in Table 7. Testing of the effects of the work up schedules was begun with Group B divers because Group A's previous 120/40 dive may have resulted in working these divers up thus increasing their toelrance to DCS. Group B, who had done no diving within the previous 2 weeks, was able to dive every day for 3 consecutive days, diving the two work-up dives and then the 120 FSW/40 min schedule. The incidence of DCS on the 120/40 schedule was much lower than that which occurred during Group A's initial dive (1 DCS in 16 man dives vs 7 cases in 17 man dives) which indicated a rather powerful work-up phenomenon. It was surprising that there was 1 case of DCS during the 80 FSW/50 min dive, a dive considered to have almost no decompression stress. The following week Group A dove the work-up dives (where surprisingly 1 case of DCS occurred on each of the workup dives) followed by the 120/40 schedule. The 11 day layoff since the initial 120/40 Group A dive was considered sufficient to allow any increased DCS tolerance The incidence of DCS was lower than the from that dive to have worn off. initial divé but higher than the Group B incidence (Table 7). If one assumes that DCS follows a random (binomial) distribution then the expected incidence of DCS on the 120/40 schedule for Group A at the 95% confidence level fell from >60% (7 DCS in 17 man dives) to approximately 25% (1 case in 16 man dives).

The descriptions of the DCS which occurred during Phase IV are given in Table C-4 of Appendix C. The individual diving intensity is given in Table D-4 of Appendix D. Of the 7 Group A divers who got DCS on the initial 120/40 dive, two (#122, 123) did no further dives, one (#118) dropped out after completing only the 80 FSW work-up dive without incident, one (#111) did not dive the second 120/40 schedule because of DCS during a work-up dive and three (#128, 129, 137) went on to complete all work-up dives and the second 120/40Of these three only one diver (#128) experienced DCS and that was schedule. Of the 12 other Group A subjects who did not on the second 120/40 schedule. get DCS on the first 120/40 dive (#133 and 113 did not complete it because of equipment failure), two (#36 and 117) dropped out, one (#71) got DCS on the 80 FSW work-up dive and 8 (#4, 70, 113, 115, 121, 125, 133, 135) successfully completed the two workup dives and the second 120/40 dive. One diver (#134) switched to Group B and successfully completed the second 120/40. 4 new subjects entered Group A for the second set of dives. One subject (#120) had suffered DCS during the first Group B 80 FSW work-up dive and switched to Group A where she successfully completed all subsequent profiles. Three other subjects (#47 124, 131) entered Group A on Sept. 19th having never dove the initial Group A 120/40 profile but dove only the second set of Group A profiles.

Of the Group B dives, only 3 did not complete all three dives. Diver #120 got DCS on the 80 FSW work-up dive and went on to successfully complete three dives later on with Group A. Diver #53 dropped out after having successfully completed both work-up dives and diver #134 did the initial 120/40 dive with Group A then switched to Group B, completing only the 100 FSW work-up and then the 120/40 dive.

# Phase V Testing (HVAL21 Tables)

The results of the Phase IV dives indicated that HVAL13 Tables would probably be unsafe for divers who have had no recent diving experience but would probably be safer after the divers had become worked up after having doing several HeO<sub>2</sub> dives. However, the work-up dives done in Phase IV would not be sufficient to confer adequate resistance to DCS. With this in mind, Phase V was designed to test a revised computer algorithm on "un-worked-up" divers. The results of Phase V are given in Table 8. In order to minimize any work-up phenomenon divers had a minimum of 36 hours off between dives as demonstrated in Table D-5 of Appendix D. The initial lengthening of the 120 FSW for 40 min schedule using HVAL16 proved successful but a further modification resulting in HVAL21 was necessary afer 2 cases of DCS occurred on the 200 FSW for 30 min schedule. The final 60 man-dives in the 200-300 FSW range using HVAL21 resulted in only a single case of DCS. At this point the emergency air breathing procedure was tested on some 70 man dives resulting in only 2 cases of DCS.

The final result of Phase V was the HVAL21 set of MPTT's which were used to compute the set of Decompression Tables in Appendix G. Of all the dives done breathing only  $\mathrm{HeO}_2$  in Table 8, only 20 man dives on the HVAL16 200/30 profile, which resulted in 2 cases of DCS, fall outside of the final HVAL21 limits based on total decompression time. The 89 man dives which did fall within the final limits resulted in 1 case of DCS giving an expected incidence of 5.5% assuming a binomial distribution at a 95% confidence level. The 79 man dives done using air during decompression resulted in 2 cases of DCS giving an expected incidence of 8.0%.

#### UBA Oxygen, Carbon Dioxide, and Nitrogen Levels

A total of 8147 oxygen samples were obtained during Phases I-III. The values were normally distributed with a mean  $\pm$  s.d. of 0.755  $\pm$  0.069 ATA. It should be remembered that the MK 15 set point of 0.7 ATA reflects the PO<sub>2</sub> level at which PO<sub>2</sub> is added to the breathing loop, not the mean PO<sub>2</sub> level which will be somewhat higher. When the PO<sub>2</sub> samples were tabulated separately for divers who suffered DCS and those who did not, the following were obtained (mean  $\pm$  s.d.):

Divers with DCS	0.741 + 0.081 ATA	n = 254
Divers without DCS	$0.755 \mp 0.069 \text{ ATA}$	n = 7893
All Divers	0.755 + 0.069 ATA	n = 8147

The 0.014 ATA difference in mean  $PO_2$  between the two groups is physiologically insignificant. Examination of individual  $PO_2$  values showed that only one diver may have suffered DCS as a result of a low  $PO_2$  level. Diver #20 was noted to have  $PO_2$  levels from 0.31 -0.51 ATA during the 40 and 10 FSW stop during a 140/65 dive on April 19 (Appendix C, Table C-2; Table 4).

Letters key DCS to descriptions in Appendix C.

HeO<sub>2</sub> Dives 109 Man Dives 3 DCS HeO<sub>2</sub>/Air Dives 79 Man Dives 2 DCS This diver eventually suffered Type 2 DCS from that dive. A low  $PO_2$  could not be implicated as a caustive factor in other cases of DCS. Low  $PO_2$  levels were not only confined to Diver #20, two other divers who never suffered DCS were noted to have  $PO_2$  levels between 0.31-0.51 ATA for 30-100 min during Profiles #14 and #38. Thus, a low PO2 level in and of itself does not overcome the effects of individual variation.

Analysis of UBA  $\rm CO_2$  partial pressure levels was more straightforward. Values ranged from 0.0 mmHg to 7.6 mmHg. However, only 0.2% of the 6825 samples were above 3.8 mmHg and in these cases divers changed to a UBA with a fresh  $\rm CO_2$  canister. None of the divers who suffered DCS had a  $\rm PCO_2$  above 3.8 mmHg on any sample.

Nitrogen partial pressures were difficult to analyze because of the wide inter-subject variability and because the partial pressure was constantly decreasing throughout the dive. Nitrogen partial pressure samples taken during the first 10 min of time at each of the depths used during Phase I-III testing ranged from mean values of 0.31 to 0.17 ATA with standard deviations as high as 50% in some instances. Nitrogen partial pressure variation was due to many uncontrolled variables such as diver lung volume when he began breathing on the MK 15 and the amount of UBA offgassing from leaks and face mask clearing. The mean nitrogen partial pressure taken during the first 10 min at depth was depth independent and the mean of the 11 means at each depth was 0.24 + 0.04 ATA. Nitrogen partial pressures for the divers who suffered DCS did not appear unique in any way and no particular relationship between high nitrogen partial pressure and DCS was evident. Nitrogen partial pressures taken during decompression were generally less than 0.10 ATA and dropped with each stop as would be expected from UBA offgassing. variability in these samples precluded analysis at this time.

In summary, UBA  $0_2$ ,  $0_2$  and  $0_2$  levels appeared to play little or no role in the subsequent development of DCS except for one diver who suffered DCS after having a low  $0_2$  during decompression. The decompression model developed as a result of this dive series was adjusted to provide safe dives given the wide variation in nitrogen partial pressures. Operationally, divers are instructed to exhale completely (rather than inhaling as done in this study) before going on their UBA which should reduce nitrogen partial pressures below the levels encountered in this study. As is evident from the longer decompression times required when using a nitrogen diluent (4), reduction of nitrogen partial pressure when using a helium diluent will be beneficial.

#### DISCUSSION

The goal of this study was to produce a computer algorithm which could compute acceptably safe 0.7 ATA constant  $PO_2$  in He decompression tables to depths of 300 FSW. Since these tables would be used mainly by EOD divers and since the EOD diver will be doing mainly single square dives, no repetitive diving was done at this time. No-decompression dives were tested first to establish the surfacing MPTT values, the ones which are in the first row of the MPTT Tables (Appendix E). Only when these had been firmly established did the study move on to test decompression dives. The MPTT Tables HVAL01-09 show 9 halftime tissues. These 9 tissues were a carryover from the MK 15/16 DCM as it was used to develop an  $N_2O_2$  algorithm (4) but as testing progressed it was

found that halftimes beyond 120 min were unecessary for computation of safe decompression schedules, and only 6 tissues were used for HVAL11 - HVAL21.

Up through HVALO9 the saturation/desaturation ratio (SDR) for all tissues At this point the SDR should be considered a strictly empirical variable which can be used to slow tissue offgassing and thereby lengthen decompression without affecting the surfacing MPTT's. In the EL-MK 15/16 DCM the tissue halftime shown in the MPTT Tables is the halftime for gas uptake. During desaturation the tissue time constant (K) is multiplied by the SDR, so if the SDR is less than 1.0 the tissue halftime  $(T_{1/2} = ln(2)/K)$  increases. In developing the HVAL13 MPTT's from HVAL09, only the 120 halftime surfacing MPTT was changed in HVAL11, all other adjustments were made to the SDR (Appendix E). The HVAL13 SDR's were retained in HVAL16 and HVAL21 and adjustments made only in the MPTT's. Note that the Blood Parameters (Appendix F, F-1; Appendix G, G-4, G-28), which are assumed constant and independent of depth, were the same values used in developing the  $N_2 \mathbf{0}_2$  decompression tables (5) for all decompression computations in this study. The adjustment for the MPTT's with increasing depth was the same for all tissues and was made by adding a constant 12 FSW for each 10 FSW increase in depth for all HVAL's This was done to make the model fit the HeO2 saturation through HVAL16. excursion limits (11). In developing HVAL21 this depth adjusment was reduced to 11 FSW for each 10 FSW of depth increase. The implications of this adjustment on the final model will be discussed later.

## Development of No-Decompression Limits

A summary of all dives done in developing the no-decompression limits was given in Table 3. This effort encompassed all the dives of Phase I and the first 90 man dives of Phase II using HVAL06. In general, the no-decompression limits are controlled by the first row of MPTT's in each MPTT Table, the so-called surfacing values. Development of no-decompression limits, therefore, concerned itself only with these values, all other MPTT's being irrelevant for no-decompression dives.

HVAL01 was designed to approximate the previously established least conservative  ${\rm HeO_2}$  no-decompression limits using a 25% fixed FO<sub>2</sub> in helium established during development of the MK 6 mixed gas SCUBA tables, (Fig. 2, ref. 12). Since these limits had already been tested, this was assumed to be a reasonable starting point. Using a 25% fixed FO<sub>2</sub>, the EL-MK 15/16 DCA using HVAL01 predicts no-decompression limits of 129 min at 60 FSW, 47 min at 100 FSW, and 20 min at 160 FSW. The no-decompression limits from Fig. 2 of reference 12 are 134 min at 60 FSW, 48 min at 100 FSW, and 19 min at 160 FSW. When a constant 0.7 ATA PO<sub>2</sub> was substituted for the constant 25% FO<sub>2</sub> in the EL-MK 15/16 DCA the no-decompression limits were 129 min at 60 FSW, 35 min at 100 FSW, and 11 min at 160 FSW.

During Phase I and Phase II testing, the single case of DCS which occurred afer the 160 FSW dive no-decompression indicated that this limit could probably not be extended beyond 11 min but the absence of DCS following the 60 FSW and 100 FSW no-decompression dives indicated that the predicted limits could be extended (Table 3). The 60 FSW no-decompression limit was successfully extended to 147 min but the 100 FSW limit could not be extended to 42 min, and in Phase I it was evetually backed off to 34 min. The 60 FSW no-decompression limit stayed at 147 min and the 80, 140, 160 and 200 FSW

limits were not changed significantly during Phase I. The initial testing of the 25 min no-decompression limit at 120 FSW using HVALO3 produced a rather severe case of Type 2 DCS in one subject (Annex C, Table C-1, Diver #35) which eventually led to progressive shortening of this no-decompression limit to 20 min.

At the end of Phase I testing, selected dives at 60, 100, and 120 FSW were done in warm (71°F) water to address the hypothesis that cold water would decrease gas uptake (due to decreased peripheral blood flow) and thus allow longer no-decompression limits than could be obtained in warm water. The incidence of 1 case of DCS in 57 man dives, due to the one minor case of DCS which occurred after a 100 FSW no-decompression warm water dive, was not judged significantly different from the cold water experience so the above hypothesis was not accepted and all further diving was done in cold water.

At the completion of Phase I, it was felt that safe no-decompression limits had been established at 60, 80, 140 and 160 FSW. In reviewing Phase I results, further testing at 100 and 120 FSW was deemed necessary to verify the safety of these no-decompression limits. It was also decided that retesting the 200 FSW no-decompression limits was necessary because (as discussed previously) the procedure used to do these dives (leaving the bottom when the SAD increased from 0 to 10 FSW) caused the divers to surface 1-2 min after the model predicted surfacing was possible (Fig. 2). While this occurred for all no-decompression dives, the difference for the 200 FSW dives was especially significant considering the short no-decompression time. The procedure was changed during Phase II as previously discussed to more closely follow the decompression model (Fig. 3). Additionally, the frequency and severity of the Type 2 DCS which occurred during Phase I testing caused a more conservative approach to be used in computing decompression schedules for subsequent Five of the 16 cases of DCS from Phase I were Type 2 and of these five, three had frank weakness and one of these three also had bladder dysfunction requiring an extended treatment. In testing of the N202 version of the MK 15/16 RTA there were 6 cases of Type 2 DCS, all occuring during Phase I N<sub>2</sub>O<sub>2</sub> testing (3) with no Type 2 cases during Phase II N<sub>2</sub>O<sub>2</sub> testing (4). Also, of the Type 2 cases which did occur during N2O2 testing, only one was of a severity comparable to the cases experienced in this study.

Phase II testing started out with no-decompression tables based on HVAL06 which was designed to specifically reduce the 100 FSW and deeper no-decompression limits, but which as a side effect also reduced the 80 FSW limit by 6 min (Annex H). Surprisingly, DCS occurred after the 100 FSW no-decompression dive even with a reduction of 2 min in the no-decompression limit but the one Type 2 case was pain with accompanying paresthesia and no signs of weakness or other CNS involvement. The thirty DCS-free dives on the 120/19 no-decompression schedule and the single Type 1 DCS on the thirty 200/6 no-decompression dives were considered an acceptable indication of the safety of these dives.

#### Development of HVAL13 Decompression Tables (Phases I-III)

#### Theoretical Considerations:

During Phase I testing and the initial no-decompression portion of Phase II testing, attention had been focused only on the surfacing MPTT values and

in HVAL01 through HVAL06 these MPTT values increased by 10 FSW for each 10 FSW increased in depth as they had been in developing the  $N_20_2$  algorithm (4). HVAL07 was the initial MPTT Table modification for decompression dives and led to HVAL09, 11, 12 and eventually HVAL13.

In developing HVAL07, the surfacing MPTT values for HVAL06 were retained but the depth increment increase was changed. In determining what the depth increment increase in MPTTs should be, certain aspects of saturation  ${\rm HeO_2}$  diving were considered. The first consideration was the saturation decompression rate, which for the EL-MK 15/16 DCM is constant as long as the  ${\rm PO_2}$  is constant. Current U.S. Navy saturation diving practice uses a decompression rate of 6 FSW/hr until a depth of 200 FSW is reached, 5 FSW/hr to 100 FSW, 4 FSW/hr to 50 FSW and 3 FSW/hr to the surface. Decompression is only done 16 hours out of each 24 so all these rates should be multiplied by 2/3 to get a mean rate. Decompression from 1000 FSW using current U.S. Navy saturation decompression rates takes 273.75 hours if one begins decompression from 1000 FSW without doing an upward excursion. This is a mean rate of 3.65 FSW/hr. The equation for the rate of tissue offgassing for the EL-MK 15/16 DCM is:

# $dP/dT = K \cdot (2.8 - PO_2)$

Using a PO<sub>2</sub> value of 0.40 ATA (13.2 FSW, where 33 FSW = 1 ATA) and a value of -3.65 FSW/hr for dP/dT and solving the above equation for K gives a value of 0.351 hrs<sup>-1</sup> which corresponds to a theoretical tissue halftime of 118 min. This means that to explain the  $\mathrm{HeO}_2$  decompression rates with the EL-MK 15/16 DCM, tissue halftimes above 120 min are not needed. This offgassing rate of 3.65 FSW/hr will only apply if every 1 FSW of offgassing allows an ascent of 1 FSW. This means MPTT's must increase 10 FSW for each 10 FSW increase in depth. If more than 1 FSW of offgassing is required, the ascent rate will be slowed proportionally.

The other aspect of saturation decompression which was considered in developing HVAL07 was the unlimited duration upward excursion limits. limits should provide an estimate as to what the maximum permissible tissue tension is at the post excursion depth since all tissues will have been saturated at the initial storage depth. The results of this analysis are given in Table 9. Note that all partial pressure units have been converted to units of FSW where 33 FSW = 1 ATA = 760 mmHg. The Inert Gas Load column shows the computed inert gas tension after saturation at the initial depth. keeping with the assumptions of the EL-MK 15/16 DCM inert gas tension was assumed equal to ambient pressure less alveolar 02 and CO2 tensions. surfacing MPTT value of 50 FSW for the 120 min tissue means that at a PO2 of 0.4 ATA (13.2 FSW), direct ascent from a saturation depth of 32 FSW would be possible (50 + 13.2 + 1.5 - 33 = 31.7) assuming a  $CO_2$  partial pressure of 1.5 FSW. Using a surfacing tension of 50 FSW and a depth increment increase of 12 FSW increase in MPTT for each 10 FSW increase in depth gives a maximum permissible tissue tension of 230 FSW for a depth of 150 FSW and 410 FSW at a depth of 300 FSW (remember in the MPTT table the value in each row is the maximum value allowed before ascent to the next shallower depth can be done, thus the MPTT values in the 160 FSW column are the tensions which must be reached before ascent to 150 FSW can be done, or conversely they are the maximum tensions allowed at 150 FSW without violating the ascent criteria).

TABLE 9

COMPUTED INERT GAS LOADS AT POST EXCURSION DEPTHS

Initial Depth (FSW)	Final Depth (FSW)	Inert Gas Load (FSW)
220	150	238
400	300	418
740	600	758
1000	835	1018

$$P_{A_{CO_2}} = 1.5 \text{ FSW}$$

$$P_{A_{0_2}} = .4 \text{ ATA} = 13.2 \text{ FSW}$$

Note: All partial pressures are given in FSW where 33 FSW = 1 ATA = 760 mmHg.

To further assist in establishing maximum permissible gas tensions at depth, some additional data gathered during development of the unlimited saturation limits was considered (13). In that series an upward excursion to 300 FSW was possible after saturation at 400 FSW. However, after saturation at 300 FSW, a 3 hr downward excursion to 450 FSW produced mild DCS upon return to 300 FSW. This indicated that the maximum 450 FSW excursion limit from a 300 FSW storage depth was about 3 hours. Referring to Table 9, the maximum inert gas tension at 300 FSW was 418 FSW. At a depth of 450 FSW the inert gas tension at a PO<sub>2</sub> of 0.4 ATA would be (450 + 33 - 14.7 = ) 468.3 FSW. In the EL-MK 15/16 DCM, gas uptake is given by the equation:

$$P = P_A - (P_A - P_I) \cdot e^{-K \cdot T}$$

where:

 ${
m P}_{A}$  is ambient inert gas tension.  ${
m P}_{I}$  is initial inert gas tension. K is the tissue time constant. T is time in min.

Using a value of 468.3 for  $P_A$ , 318.3 for  $P_I$  (saturation value at 300 FSW) and 418 FSW for the final gas tension (P) and 180 min for T and solving for K one obtains a value of  $6.070 \cdot 10^{-3} \, \text{min}^{-1}$  which represents a tissue halftime of 114 min. So a maximum permissible tissue tension for the 120 min of 418 FSW would predict a maximum 450 FSW downward excursion time of about 3 hours from a saturation depth of 300 FSW.

The above analysis is based on the assumptions used in developing the EL-MK 15/16 DCM (4) and is presented to give a thorough picture of the considerations used in constructing HVALO7. The object was to develop a decompression model which could explain as much as possible of the current helium-oxygen decompression data in the literature. While a lot of rationalization went into constructing HVALO7, some of the initial data fitting had to be compromised in developing subsequent MPTT's as the reality of actual test results accumulated.

#### Decompression Schedule Testing:

The HVALO7 MPTT proved remarkably long lived and survived most of Phase II testing (Table 4). When the 180 FSW for 45 min schedule was tested the 4 cases of DCS which occurred caused the 120 min surfacing tension to be reduced from 50 FSW to 48 FSW. Longer tissue surfacing tensions were reduced but these longer tissues never controlled any stops during that dive. resulting MPTT table was HVAL09. The main effect of HVAL09 was to lengthen the 180 FSW for 45 min schedule from 146 min total decompression time to 164 min (Appendix H). The 100/60, 120/40, 150/30, 200/10 and 200/30 schedules were unchanged but other schedules were lengthened slightly. HVAL09 appeared successful until the last dive of Phase II which was a 120 FSW for 40 min dive (Table 4). Diver #40 initially noted some shoulder discomfort 2 min before surfacing which increased after surfacing. Hip pain and upper extremity weakness developed and the diver was recompressed within 10 min of surfacing where complete relief was noted on arrival at 60 FSW. A complete

neurological examination performed at 60 FSW by a Diving Medical Officer was normal. A Treatment Table 6 was completed and the diver appeared normal upon surfacing. Within 10 min after surfacing, severe CNS DCS occurred leading to a 36 hour stay at 60 FSW with a 30 hr decompression. After several follow-up treatments, the diver eventually became completely asymptomatic 8 months later (Annex C, Table C-2). It should be noted that this diver showed a remarkable sensitivity to DCS from Phase I (Appendix D, Table D-1).

In planning Phase III, the fact that only one diver suffered symptoms of DCS on the 120/40 schedule and that he appeared unusually susceptible to DCS led to lengthening of that schedule by only 3 min with HVAL11. Since the no-decompression limits had appeared safe, the 120 min surfacing tension was restored to 50 FSW but its SDR was reduced from 1.00 to 0.83. This had the effect of making this tissue act like a 145 min tissue during offgassing but giving HVAL11 the same no-decompression limits as HVAL06 with the exception of the 80 FSW limit which was increased approximately 6 min to 67 min. Since the 120/40 schedule was the last one dove on Phase II and had produced DCS, it was decided to retest that schedule before moving on to deeper, longer schedules. The resulting 4 cases of DCS which occurred in the first 30 man dives of Phase III was totally unexpected since the shorter Phase II schedule had produced only 1 DCS in 30 man dives. As a result of this high DCS incidence, HVAL12 was developed which kept the same suracing MPTT values as HVALll but had the SDR values for the 5, 10 and 20 min tissues reduced. Since both stops of the 120/40 schedule were controlled by the 20 min tissue this lengthened that schedule another 5 min to a total decompression time of 40 min. A total of 40 man full 8 min increase over the Phase II HVAL09 schedule. dives were done on the HVAL12 schedule with no symptoms of DCS (Table 5). All divers who had Type 1 symptoms fom the HVAL11 schedule dove this HVAL12 schedule (Appendix D, Table D-3, Diver #90, 100 and 102). The fourth diver, who had developed Type 2 DCS (#98), reentered the series 5 days later. HVAL12 proved very successful producing only 4 easily treatable Type 1 symptoms of DCS in 309 man dives.

HVAL13 was developed from HVAL12 by increasing the SDR's of the 5 and 10 min tissue to shorten the deeper stops of planned 250 and 300 FSW dives. This empirical shortering of decompression times for these two schedules was simply a calculated guess. HVAL13 resulted in some change in stop time distribution but no change in total decompression time for the 150/30, 160/25, and 180/25 schedules, and only minor shortening of total decompression time for the 160/50, 180/40 and 180/45 schedules (Appendix H). The 250 and 300 FSW schedules proved remarkably safe considering their depth and long decompression times. Of the two cases of DCS which occurred, the one reported as Type 2 may very well have not been DCS at all but a transient postural hypotension. Although the diver had a transient episode of mild syncope 50 min post dive, he rapidly returned to normal just before treatment was begun and had no symptoms other than mild fatigue at that time (Appendix C, Table C-3, diver #97).

## Effects of Diving Intensity:

During Phase III testing, some attention was paid to whether or not DCS incidence might increase with a decrease in diving activity. On Friday, August 20 and Monday August 23, 30 man dives were dove each day on a 160/25 schedule (Table 5). The one case of DCS which occurred on the Monday was a

shoulder pain which responded only minimally to recompression and was most likely a muscle sprain. So, this 2 day layoff did not significantly increase the incidence of DCS. After completing dives on August 25, there was a 4 day layoff and on 30 August, 20 man dives on the 160/25 schedule (Table 5) showed no DCS (30 man dives were attempted but one set was aborted because of a computer failure). It appeared that even a 4 day layoff did not change the incidence of DCS, although it is admitted the number of man-dives upon which this conclusion is based is small.

## Deep Stop Dives:

The EL-MK 15/16 DCM predicts that tissue offgassing at 20 FSW breathing a 0.7 ATA  $PO_2$  will be the same as at 10 FSW. Also, the MPTT's are such that the surfacing MPTT values could be reached at a 20 FSW stop. The 29 DCS-free dives done during Phase II where the last decompression stop was taken at 20 FSW validated these predictions. Operationally, being able to take the last decompression stop at 20 FSW is useful, especially in heavy seas. Since the total decompression time did not change, after completing the mandatory 20 FSW, one need only remain at any depth between 20 FSW and 10 FSW for the indicated 10 FSW stop time.

At this point, it was felt that HVAL13 could be used to generate a set of operationally useful and safe tables. A complete set of these tables is given in Appendix F. The overall safety of the HVAL13 Tables was estimated as a 3.9% or less expected incidence of DCS (Table 6a). This is essentially the same as the 3.5% expected DCS incidence from development of the constant 0.7 ATA  $PO_2$  in  $N_2$  Decompression Tables (5).

#### Phase IV Testing

#### Initial Considerations:

Having developed a computer algorithm which was thought to compute decompression tables of acceptable safety preparations were made to test diving procedures using HVAL13 Tables in the open sea. One of those procedures was an emergency procedure (EP) designed to address the problem of a closed-circuit UBA failure during decompression. Plans called for supplying the diver with compressed air from the surface via an open circuit SCUBA regulator and letting him breathe air during decompression. Since this procedure involves switching inert gas during decompression, it should However, in this EP no change in theoretically speed up decompression. decompression schedule was planned and the dive would continue decompressing on the HeO2 schedule while breathing air. Two teams of divers, Group A and Group B, were used for Phase IV testing, where this procedure was to be tested. In training for this testing, a 120/40~0.7 ATA constant  $P0_2$  in He decompression schedule was dove by Group A in the OSF using the same real time algorithm as used in Phases I-III. The resultant DCS incidence of 7 cases in 17 man dives was unexpected (Table 7) and Group B did not dive the profile. A complete reevaluation of Phase I-III testing was then begun. Phase III testing, it was noted that a similar incident occurred on the HVAL11 120/40 schedule when dove as the first profile of that series (Table 5). retrospect the large increase in DCS incidence on the 120/40 schedule as the very first one in Phase III (4 cases in 30 man dives) compared to Phase II (1 case in 30 man dives) may have been due to an increased DCS tolerance in Phase II divers, the so called workup phenomenon.

#### Workup Phenomenon:

Phase II diving did not start with decompression dives but with 90 man dives on no-decompression dives. Most divers dove every day during the first three days of Phase II, had one day off and then dove again (Appendix D, Table D-2). Based on this diving intensity, it appeared (in retrospect) that the Phase II divers were well worked up by the time decompression dives with higher decompression stress were encountered. Applying these considerations to Phase III testing the 5 min increase in decompression time on the HVAL12 120/40 schedule may have been only partially responsible for the 40 DCS free man dives (Table 5) using that schedule. The other factor may well have been that the HVAL11 120/40 schedule dove as the first Phase III dive provided enough of a workup to increase diver resistance to DCS during the subsequent HVAL12 120/40 schedule testing.

Having postulated that a workup phenomenon was present, the next step was to determine its magnitude and duration. As previously noted, no increase in DCS incidence was noted during Phase III testing even after a 4 day layoff so it was postulated that once a diver was worked up it would take longer than 4 days for the effect to subside. The next problem was to determine how to work up a diver. The Phase II no-decompression profiles did not seem to have resulted in any higher DCS incidence compared to Phase I when dove as the first profiles in Phase II and it appeared that they were sufficient to work Based on this consideration, it was decided to see if two less up a diver. than no-decompression workup dives would be sufficient to decrease the DCS incidence on the 120/40 schedule to acceptably safe levels. The dives selected as workup dives were 80 FSW for 50 min and 100 FSW for 30 min. choices were somewhat arbitrary but the 80/50 dive was judged to have negligible decompression stress since it was 17 min shorter than the tested no-decompression limit and the 100/30 was judged slightly more stressful being only 2 min shorter than the no-decompression limit (Appendix H, Table H-1).

The plan was to do the two workup dives followed by the 120/40 schedule with no more than 2 days elapsing between each dive. Since it was desirable to test these workup dives with as fresh a group of divers as possible, testing was restarted with Group B divers, who had not dove the initial 120/40 schedule as had the Group A divers. Group B testing was done over 3 consecutive days (Table 7). The initial results looked encouraging with only 1 case of DCS in 16 man dives on the 120/40 schedule. It was surprising that there was a case of DCS on the 80/50 workup schedule but it was an easily treatable Type 1 as was the single case on the 120/40 dive. After an eleven day layoff, which was presumed sufficient time to eliminate any carryover effects from having dove the first 120/40 schedule, Group A reentered the dive They began their workup dives with only 14 of the original group remaining and 4 new divers joining the group. Out of the seven divers who got DCS on the first 120/40 dive, five started the subsequent series of workup dives. The results were not as encouraging as the Group B dives. two Type 2 DCS during the workup dives and two Type 2 DCS during the final 15 man dives on the 120/40 schedule.

Diver #71 who suffered DCS on the 80/50 Group A workup dive had made 8 dives during Phase II without experiencing DCS, so one could not classify him as a sensitive diver. Diver #11 who suffered DCS on the 100/30 Group A workup dive had not participated in any other phase but did get knee pain on the initial Group A 120/40 dive. Looking at the two divers experiencing DCS on the second Group A 120/40 dive, one (#128) had DCS on the initial Group A 120/40 dive and the other (#125) had no previous DCS. Neither of these divers Both of these divers went on the Phase V had participated in earlier phases. without problems. Diver #120 who suffered DCS on the first Group B 80/50 workup dive switched to Group A and completed all three dives without (This diver did, however, develop a severe Type 2 symptom 7 months later during Phase V [Appendix C, Table C-5]). The distribution of DCS among the Phase IV divers indicated a random occurrence with no identifiable Even absence of DCS in a previous dive series (Diver predisposing factors. #71) did not guarantee avoidance of DCS during Phase IV.

Phase IV results clearly showed a workup phenomenon was present and that even workup dives with bottom times less than no-decompression limits could significantly reduce the incidence of DCS on the 120/40 schedule. even with these workup dives the 120/40 schedule attained nowhere near its previous safety record of 40 DCS free dives and it was concluded that the 80/50 and 100/30 sub-no-decompression dives did not provide sufficient workup. Analysis of Phase II dives showed that diving 4 of the HVAL13 no-decompression dives within a 5 day period may have provided sufficient workup for the Phase II decompression dives. During Phase III diving a single 120/40 dive using HVAL13 may have provided sufficient workup for the following 120/40 dive. Phase IV, whatever workup effect the first 120/40 dive had had for Group A divers was lost afer the 11 day layoff since the DCS incidence in this group was similar to that in the un-worked up Group B divers. Based on this and the Phase III dives done to investigate the effect of diving intensity on DCS as previously discussed, it was concluded that the effects of any workup dives wear off between 5 and 10 days.

This workup phenomenon or adaptation to decompression sickness is not new and has been described in tunnel workers and divers (19, 21). It has also been described in U.S. Navy diving. In 1970, Alexander, Flynn and Summitt (15) set out to test some revisions of the surface-supplied U.S. Navy HeO2 These revisions had been calculated in 1968 using the decompression tables. method described by Workman (16) and generally required more decompression than the then current tables (which are the tables which currently appear in Volume II of the U.S. Navy Diving Manual). Three revised tables were tested. Twelve man dives done on a 141 FSW/60 min table were DCS free. This table had 15 min less decompression time than the standard  $HeO_2$  decompression table. The next 36 man dives were on revised 196 FSW/60 min and 257 FSW/50 min decompression tables which were about 25% longer than the standard tables. total of 9 cases of DCS resulted, all reported as Type 1. At this point, no This high incidence of DCS surprised the authors further diving was done. since their analysis showed the DCS incidence in the Fleet to be 0.065-0.83%. The authors did not speculate on the reasons for this unexpectedly high incidence of DCS on the longer revised decompression tables, but one explanation might be that the divers had not been sufficiently worked up.

A more recent unpublished analysis by NEDU of HeO<sub>2</sub> dives done in the Fleet during the period 1968-1983 using the 200 FSW or deeper Surface Helium-Oxygen Partial Pressure Tables showed that 20 cases of DCS occurred in the 147 man dives done with bottom times 30 min or more. There were 4484 man dives with bottom times less than 30 min and only 12 cases of DCS occurred in this group. While it will be admitted that only the deeper HeO<sub>2</sub> schedules were analyzed, the DCS incidence for bottom times 30 min and greater is considerable. No published data is available on the DCS incidence observed during initial testing of the HeO<sub>2</sub> surface-supplied decompression tables but based on the literature cited by Alexander et al (15) it would be expected to be lower than the 13.6% incidence observed since 1968.

In testing of an improved Venturi for the MK V  $\rm HeO_2$  recirculator, Van Der Aue et. al. (18) performed 108 man dives at depths from 225 to 429 FSW resulting in 4 cases of DCS giving an incidence of 3.7%. Bottom times for these dives were generally 20 min. In the above NEDU analysis there were 193 dives done with bottom times of 20 min and there were no cases of DCS reported for these dives. One would conclude, therefore, that the DCS incidence on Surface-Supplied  $\rm HeO_2$  Decompression Tables would rise considerably at bottom times greater than 20 min.

During initial evaluation of the Surface-Supplied HeO2 Decompression Tables, a DCS incidence approaching 13.6% would undoubtedly have caused the troublesome schedules to be revised. At this point one can only speculate on the reasons for this high incidence of DCS on the deep, long HeO2 Surface-Supplied Decompression Tables observed since 1968. One explanation is that divers used for initial table testing had been worked up either by previous air diving intensity or from the dives done during the initial table testing. These "worked up" divers then were able to safely dive schedules which would have caused a much higher DCS incidence in "fresh" divers. During the study of Alexander, Flynn and Summitt (15) the divers used were probably "fresh" and thus had not acquired the postulated increased resistance to DCS. relatively small number of deep HeO2 dives of 30 min or more bottom time done in the Fleet since 1968 speaks of a relatively low diving intensity and divers who had not had enough recent diving to become "worked up". Clearly, a more thorough analysis of U.S. Navy Fleet diving is necessary before any firm conclusions can be drawn from Fleet diving experience.

# Phase V Testing

The results of Phase IV indicated that HVAL13 Tables were safe only for worked up divers and that the two workup dives tried in Phase IV would decrease the incidence of DCS but not to the desired level. Two choices were available at this point; one was to find a workup procedure which would allow HVAL13 schedules to be dove safely and the other was to develop a set of MPTT's which would generate decompression schedules which could be dove by "un-worked up" or "fresh" divers. Since the EOD community tends to dive in isolated areas and many times on short notice, it was decided to take the latter choice and develop a "fresh-diver" MPTT Table. In planning Phase V it was realized from the outset that repeating the 1394 man dives done up to this point was unrealistic and impractical. Since the divers would be getting worked up after their fist dive, testing of more than a few schedules would give little additional information concerning "fresh" divers. So it was

decided to construct a new set of MPTTs then immediately test the 120/40 decompression schedule as the first dive. If that proved safe then two other schedules 200 FSW and deeper would be tested. These deep schedules were chosen because they had been done at the end of the previous phases when the divers were presumably fully worked up and may have appeared safer than they actually were. Finally, the emergency decompression procedure using air initially slated for Phase IV testing would be tested if the  ${\rm HeO}_2$  schedule testing proved safe.

The subjects for Phase V had only had a total of two 30 FSW for 60 min exposures in the week preceding the dive for training purposes, and had no  ${\rm He0}_2$  exposures or dives beyond no-decompression air diving in the two week period before that. The diving schedule was set up to give subjects a minimum two full days off between dives giving a inter-dive period of 60 hours. This intensity was exceeded by only two subjects during the  ${\rm He0}_2$  portion of the study; subject #147 dove profile 38 and 43 with only 36 hrs between dives and subject #161 dove profile 38 on two consecutive days (Appendix D, Table D-5).

The initial set of MPTTs developed for Phase V was HVAL16 (Appendix E). Development of HVAL16 began with a reconsideration of no-decompression limits. The Mixed Gas HeO2 SCUBA Decompression Tables (also called the MK 6 HeO2 Tables since that was the UBA they were used with) were initially developed using 20%  $0_2$  (17) and later 25%  $0_2$  (12). Up to this point, changing the P0<sub>2</sub> level had been assumed in the EL-MK 15/16 DCM to cause no change in venous oxygen tension. If this is the case then only the tissue inert gas tension need be considered in deriving the MPTT values since changes in arterial 02 tension would not change tissue 02 tension. At this point our thinking on this matter was changing and changes in venous PO2 as a function of arterial PO2 were being considered for the next version of the EL-MK 15/16 DCM. Also, our thinking was now to consider total tissue gas tension in developing ascent criteria rather than just inert gas tension. Thus, if the PO<sub>2</sub> is raised, a portion of the fall in inert gas tension would be offset by a small increase in venous oxygen tension. When diving a constant PO2 breathing mix as supplied by the MK 15 or MK 16, there is no variation in arterial oxygen tension so changes in venous PO2 need not be considered. However, when using the EL-MK 15/16 DCA to compute decompression tables on a constant  $\rm FO_2$  for comparison with existing tables, these venous oxygen level changes must be considered. A PO2 of 0.7 ATA equals an FO2 of 25% at 60 FSW. Since the EL-MK 15/16 DCM assumes venous oxygen tension to be constant it should underestimate total tissue tension below 60 FSW using a 25% FO2 since the model will not raise venous PO2 in the face of an increased arterial PO2. Conversely, at depths shallower than 60 FSW the EL-MK 15/16 DCM will overestimate total tissue gas tension since it will not cause the venous Thus, if the EL-MK 15/16 oxygen tension to fall as the inspired PO2 falls. DCA is used to compute no-decompression limits comparable to the Mixed Gas SCUBA HeO2 (MK 6) no-decompression limits (13,17), they should be very close at 60 FSW and the EL-MK 15/16 DCA limits should be shorter shallower than 60 FSW and longer deeper than 60 FSW. Table 10 compares the no-decompression limits for HVAL16 and HVAL21 using the EL-MK 15/16 DCA and an FO2 of 25% with the MK 6 HeO2 SCUBA tables. At the 170 FSW depth, the no-decompression limit as computed by the EL-MK 15/16 DCA is controlled by the 5 min tissue at an inspired PO2 of 1.54 ATA. If one postulated an increase in venous oxygen

tension of 0.15 ATA at this depth when the inspired PO2 increased from 0.70 to 1.54 ATA, and one considers that the MPTTs represent total gas tension instead of inert gas tension only, the no-decompression limit would fall to 10 min. At the shallow end the 50 FSW no-decompression limit is controlled by the 120 min tissue. The PO2 at 50 FSW is 0.63 ATA and if one postulates a fall of 0.02 ATA in venous  $\overline{0}_2$  when inspired PO<sub>2</sub> decreases from 0.7 ATA to 0.63 ATA then the 50 FSW no-decompression limit will fall by 1 min to 180 min. line of reasoning was used to rationalize decreasing the 5 min surfacing MPTT from an HVAL13 value of 120 FSW to 115 FSW in HVAL16 and decreasing the 120 min surfacing MPTT from 50 to 48 FSW. Without these decreases much larger changes in venous oxygen tensions would have had to be postulated in order to reconcile the HVAL16 25%  $F0_2$  no-decompression limits with the MK 6  $He0_2$ It was also decided to increase the total decompression time for the 120/40 decompression schedule by 10 min and since all stops for this dive would be controlled by the 20 min tissue, its surfacing MPTT had to be reduced from 82 to 77 FSW to obtain the desired increase. The 80 min tissue controlled the 60 FSW no-decompression limit and a value of 55 FSW for the surfacing MPTT gave a limit of 133 min which seemed conservative based on Phase I testing, but which was close to the MK 6 HeO2 limit.

Initial testing in Phase V began using HVAL16. The SDR's and the 12 FSW increase in MPTT with each 10 FSW depth increase remained the same in HVAL16 The first 29 man dives on the 120/40 schedule as they were in HVAL13. resulted in no DCS and at least the 20 min halftime tissue MPTT adjustment was declared a success (Table 8). All of the 10 min increase in decompression time on this schedule was at the 20 FSW and 30 FSW stop. The next schedule tested was profile #38 which was 200 FSW for 30 min. In spite of a 17 min increase in total decompression time over the HVAL13 profile (Appendix H), there were 2 cases of DCS in 20 man dives, one a bizzare case of retrograde This diver had suffered Type 1 DCS previously in Phase IV on the 80/50 workup dive but did complete two other workup dives and an HVAL13 120/40 schedule without problems.

In attempting to lengthen the 200/30 schedule, several techniques were All SDR's for halftime tissues 20 min and longer were decreased to 0.71 which inreased the 200/30 total decompression time 13 min at the 10 FSW Other variations in changing the SDR values were tried but in the end it was decided to keep the HVAL16 SDR's and decrease the MPTT depth increment increase from 12 to 11 FSW producing HVAL21. The resultant 13 min increase in total decompression time on the 200/30 schedule occurred by shifting some stop time deeper and increasing the 10 FSW stop 11 min. This strategy appeared successful and 30 DCS free man dives were done on the 200/30 schedule using HVAL21 (Table 8). The only case of DCS which occurred on HVAL21 was one Type 2 on a 260/22 schedule. This schedule started out as a 300 FSW schedule but an ear squeeze in one of the divers prevented descent below 260 FSW. his was a Type 2 DCS, the symptoms were mild, easily treatable paresthesias. At this point, no further testing of HeO2 schedules was done, it was felt that HVAL21 would increase total decompression time sufficiently so that the resultant decompression schedule would be safe for fresh divers.

### HeO2-Air Emergency Profiles:

In setting out to do the HeO2-Air Emergency Profiles, it was anticipated that no DCS would occur since the switch from HeO2 to air should increase tissue offgassing of helium. It should be noted, however, that the PO2 of all decompression stops shallower than 80 FSW was reduced below 0.7 ATA when air was breathed. This decrease in PO2 was assumed to be more than offset by the increased offgassing resulting from the change in inert gas but based on the 2 cases of DCS which did occur on these profiles this assumption may have been In testing their revised HeO2 decompression schedules, Alexander, et. al. (15) used air for decompression during stops from 100 to 40 FSW on a revised 200 FSW partial pressure for 60 min schedule. Two cases of DCS occurred after 6 man dives, the same incidence observed breathing HeO2 and 100% 02 during decompression. So even in this early study air breathing was neither detrimental or beneficial. The 2 cases of DCS which did occur during the HeO2/Air testing were not felt to be of sufficient severity to prevent using air breathing as an emergency procedure.

## Decompression Sickness

Of the 174 divers who participated in the 5 phases of this study, 43 suffered decompression sickness at least once. Table 11 shows the frequency of decompression sickness in each of the affected subjects. A total of 11 subjects suffered DCS more than once and of these two subjects had DCS more The means and standard deviations for age, height, weight and than 2 times. percent body fat of the DCS subject population and no-DCS subject population is given at the end of Appendix A. A two tailed t-test was done to see if there was any significant difference between the means of the two populations for any physical characteristics. At the 5% level of significance, the only significant difference between the two populations was mean age which was 28.4 for the DCS population and 30.5 for no-DCS population. Examination of the diving frequency and schedules dove showed no differences between the two populations so all that can be said is that in general the DCS population was younger than the no-DCS population.

Two subjects stand out from all others, accounting for 21% of all DCS. These are subjects #38 who suffered DCS on every one of the 4 dives he made and #40 who suffered DCS 5 times in 22 dives. Both of these subjects could be classified as unusually sensitive to DCS and they tended to be older (38 and 33 yrs) than the 30 yrs population mean, heavier (195 and 212 lbs vs a mean of 178), and had more body fat (26% and 23% vs a mean of 17.5%). Subject #40 suffered DCS on 4 of his first 7 dives in Phase I and appeared to make a full recovery after each one. During the 1 month interval between Phase I and Phase II, this subject paticipated in a series of 25 FSW and 40 FSW 100%  $0_2$  dives without incident. During Phase II he completed 14 DCS free dives then suffered a severe recurrence of Type 2 DCS on the last schedule, which was a 120/40 and HVAL09 (Appendix C, Table C-2). This subject required multiple follow-up treatments but eventually gained full recovery but was disqualified from further diving because of his unusual susceptibility to DCS.

#### TABLE 11

#### DECOMPRESSION SICKNESS FREQUENCY

Each entry shows total number of dives dove by each diver and, if DCS occurred, the sequential dive number on which DCS occurred in parenthesis. (Examples: Diver #29 entry of 11(3\*,10) means he did 11 dives with DCS occurring on the 3rd and 10th dive).

<sup>\*</sup> TYPE 2 DCS

<sup>@</sup> Dives 1-3 of Phase II are no-decompression dives and are tabulated in Table 3 and DCS is described in Table C-1 of Appendix C.

In this dive series, 37% of all DCS was Type 2. This is in contrast to the previously reported N<sub>2</sub>O<sub>2</sub> dive series (3,4) where only 17% of symptoms were Type 2 and of these only two (letter key c, r, in Appendix 3, page 3-3 of ref. 3) were of a severity comparable to most of the Type 2 cases here. In the dive series in this report, of the 22 cases of Type 2 DCS, 11 would be considered serious involving the spinal cord, cerebrum and midbrain, 10 less serious involving the spinal cord or perhaps only peripheral nerves and 1 presenting equivocal symptoms. These symptoms are catagorized in Table 12. While many of the symptoms listed as Severe could be referable to the spinal cord, the generalized nature of these symptoms give cause to wonder if they were mainly cerebral manifestations. The symptoms listed as Mild were unlikely to be of cerebral origin and could have been caused by spinal tract lesion or peripheral nerve root involvement.

The randomness and unpredictability of DCS in this dive series is exemplified by the occasional occurrence of severe symptoms in one diver with very mild or no symptoms in his fellow divers. On the 120/40 profile at the end of Phase II, one diver suffered severe Type 2 DCS while 29 others had no symptoms. Another example is from Phase IV where diver #71 became confused and had slurred speech after diving an 80 FSW for 50 min no-decompression profile. Initially, one would put this off as an isolated incident considering the short bottom time but the case of Type 1 DCS which occurred on this profile make this unlikely. The 2 cases of DCS in 35 man dives on this 80/50 sub-no-decompression profile point up the futility of trying to develop profiles which will produce no DCS.

The reason for the high proportion of Type 2 DCS and of cerebral symptoms diving these HeO2 schedules remains a matter of conjecture. Vann (19) has postulated that the lower solubility of helium allows higher overpressures before gas comes out of solution, but when it does, more bubbles form in a One possible prediction is that compared to N2O2 unit tissue volume. breathing, larger numbers of much smaller bubbles form when helium comes out One could postulate that certain individuals have pulmonary of solution. vascular anatomy which would allow many more of these smaller bubbles to cross the lung filter and enter the arterial circulation as tiny gas emboli. functionally patent foramen ovale would be another possibility). Once in the cerebral circulation these bubbles would act like arterial gas emboli, and many of the symptom presentations listed in Table 12 did resemble air embolism.

The raw incidence of DCS on the 1503  $\rm HeO_2$  dives done during the 5 phases of this study was 3.79%. This incidence is much less than the 6.8% raw incidence observed during both phases of  $\rm N_2O_2$  table testing and is similar to the 3.5% expected incidence using the final set of  $\rm N_2O_2$  tables (4). So overall,  $\rm HeO_2$  diving appears to have a lower incidence of DCS than  $\rm N_2O_2$  table but when symptoms do occur there is a higher probability they will be Type 2. The incidence of DCS was 2.5% when air was breathed during decompression but the small number of man-dives (79) done on these schedules makes comparison with the  $\rm HeO_2$  incidence difficult.

TABLE 12

MAJOR SYMPTOMS IN TYPE 2 DCS

		APPENDIX	MAJOR SY	MPTOMS
	DIVER #	C KEY	Severe Spinal, Cerebral	Mild, Peripheral Spinal Cord or Equivocal
	29	b	Pain, weakness	
	35	f	Weakness, loss bladder control

	150	ii		Paresthesias

<sup>(?)</sup> Equivocal symptom which may not have been DCS. See text.

## Treatment of Decompression Sickness:

All cases of DCS were treated with standard U.S. Navy Treatment Table 5 or 6 with five exceptions. Diver #120, (Appendix C, Table C-5) was compressed to 165 FSW and treated on a modified Treatment Table 4 when he showed little improvement with initial compression to 60 FSW. Modifications included breathing a  $50/50~\rm N_2O_2$  mix at 165 FSW and during decompression to 60 FSW. Immediately upon arrival at 60 FSW, the diver was given several periods of  $100\%~\rm O_2$  breathing for 25 min interspersed with 5 min air breaks until his symptoms abated over the next few hours.

Four divers were kept at 60 FSW for 10-18 hours (Appendix C; Table C-1, Diver #35; Table C-2, Diver #40; Table C-4, Divers #123, #71). Diver #71 had been compressed to 165 FSW after only partial improvement at 60 FSW and was decompressed back to 60 FSW on a Treatment Table 4 schedule where he was kept for 12 hours. The three other divers were all initially treated by compression to 60 FSW. At 60 FSW, these divers were given 100%  $0_2$  by mask for 25 min periods followed by 5 min air breaks as indicated by their symptoms. This was usually done for a maximum of 4 hours  $(8-0_2)$  breathing cycles) at which point a 4-hour air breathing period was begun. Only subject #40 got significant symptoms of pulmonary oxygen toxicity because of the large number of  $0_2$  breathing periods given.

The decompression schedule used to decompress the four divers at 60 FSW after their extended stay, as shown in Appendix C, was a 30 hour schedule developed during a series of 60 FSW air saturation dives done at NEDU. The 30 hour schedule used here was successful at decompressing both the diver and the tender who breathed only air throughout the treatment. Further testing at NEDU has shown that while the 30 hour schedule is sufficient for 18-24 hour bottom times, a 36 hour schedule is required for 96 hour stays at 60 FSW and, in fact, may be more suitable for a treatment table. This 36 hour schedule uses the same three rates as the 30 hour schedule except that the rate is changed at 40, and 20 FSW instead of at 30 and 10 FSW. This extended 60 FSW treatment table has been incorporated into Revision 1 of Vol. 1 of the U.S. Navy Diving Manual as Treatment Table 7. Full details of how treatments should be conducted are given in the new revision to the U.S. Navy Diving Manual and the development of the 60 FSW air saturation decompression schedule will be the subject of a future NEDU report.

With the exception of the modified Treatment Table 4, the only breathing gases used for treatments was air and oxygen. Although all dives were done breathing  $\mathrm{He0}_2$ , there was no observed adverse effect from compressing on air while breathing oxygen. All divers showed some improvement or complete relief on initial compression, no symptoms were exacerbated once treatment was begun. There were two notable relapses of symptoms after apparent initial resolution. These were Diver #35 (Appendix C, Table C-1) and Diver #40 (Appendix C, Table C-2), both of who suffered recurrence of serious central nervous system symptoms requiring extended treatment. Even in these cases, however, complete resolution of symptoms was eventually obtained using air treatment tables.

#### Returning to Diving After Treatments:

Divers successfully treated for Type 1 DCS were allowed to resume diving 48 hours after treatment. Divers suffering Type 2 DCS were kept off diving

for variable lengths of time depending on the severity of their symptoms and response to treatment. Generally, those divers suffering symptoms listed as Mild in Table 12 resumed diving 4 to 6 days after treatment. Of the 11 divers listed in Table 12 suffering Severe symptoms, eight did no further diving after treatment for that symptom (35, 40t, 98w, 123, 71, 125, 128dd, 120). Diver #29 was off 8 days then resumed diving and suffered a Type 1 DCS after completing 6 symptom-free dives. Diver #40(i) was off 6 weeks after his first severe symptom and completed 14 symptom-free dives before suffering another severe Type 2 symptom which eliminated him from the study. Diver #98(a) responded promptly to initial treatment and resumed diving 4 days later, completed 3 symptom-free dives then suffered another Type 2 DCS and did no further diving.

It appears that a 48 hour period of no diving after successful treatment of Type 1 DCS is sufficient for the vast majority of divers. Two divers in this series (#38 and #40) showed themselves abnormally sensitive to DCS and will be discussed separately. Of the other 41 subjects, only 9 suffered DCS more than once (12, 15, 17, 20, 56, 98, 111, 120, 128). Of these, only two divers had Type 2 DCS twice. Diver #98 had less than the 4-6 day layoff after his first Type 2 symptoms (Appendix D, Table D-3) but Diver #128 had 10 days off after his first symptom. The seven other subjects showed no particular predilection for DCS and their second bout of DCS was usually preceded by several DCS-free dives and in two cases (Divers #17 and #120) the 2 DCS incidents occurred on separate dive series.

Divers #38 and #40 presented special problems and have been discussed earlier in this section. Diver #38 had extended off periods between his three Type 1 symptoms (3 days, 5 days and 11 days) before suffering a Type 2 symptom. He suffered DCS on every dive and it appeared that no period of time off from diving would have been sufficient for this remarkably sensitive Diver #40 was off 3 days and 4 days after his two initial symptoms which were both Type 1. His third DCS occurred after only one symptom-free dive, 8 days after his previous Type 1 DCS treatment. The Type 2 component of this third bout of DCS was back and abdominal aches which responded very rapidly to minimal recompression and he was given 6 days off before resuming diving at which time he suffered another Type 2 symptom involving muscle weakness and loss of proprioception. Again he responded rapidly to treatment but did no further dives during Phase I. This diver was then a subject on 100% 02 dives to depths from 25 to 40 FSW and this activity plus the 6 week hiatus between HeO2 dive series lead to the conclusion that more than sufficient time had elapsed for complete resolution of any The ensuing 14 symptom-free dives this sub-clinical residual effects of DCS. diver did over the next 4 weeks of Phase II initially reinforced this conclusion and the severe Type 2 DCS he suffered on the last dive of Phase II was totally unexpected. It was concluded that this diver had an abnormally high predilection for DCS from HeO2 dives and should do no further diving.

The sensitivity of subjects #38 and #40 to DCS cloud the issue of how much time should be taken off after DCS occurs. As previously noted, 48 hours after successful treatment of a Type 1 DCS symptom appears a sufficient non-diving interval. Based on the response of divers #98 and #128, it appears a longer period of time should have elapsed after their Type 2 symptoms before they resumed diving. While a 5 to 6 day layoff appeared sufficient for most other divers in this series who suffered Type 2 symptoms, a 14 day non-diving

period after suffering Type 2 DCS would appear more reasonable for widespread use in operational diving. This recommendation must be caveated by saying that the symptom should have responded promptly to a Treatment Table 6 and had complete relief. Divers suffering symptoms such as those described as Severe in Table 12 should probably have even longer non-diving periods up to 4 weeks. However, as shown by diver #40, even this may not be sufficient in sensitive individuals and individuals who show an abnormally high incidence to DCS (whether Type 1 or Type 2) should probably be eliminated from further diving as soon as this increased incidence becomes apparent.

#### Final Decompression Tables

The HVAL21 Tables shown in Appendix G are the final set of tables computed by the EL-MK 15/16 DCA resulting from this study. Tables are given in feet of sea water (FSW) with 10 FSW stops and in meters of sea water (MSW) with 3 MSW stops. Ascent and descent rates for tables in feet are 60 FSW/min. The Royal Navy descent and ascent rates of 20 MSW/min (or 1 meter every 3 sec) were used for the metric tables. The EL-MK 15/16 DCA uses pressures in FSW internally so all depths were first converted to FSW using the conversion factor 0.3048 MSW/FSW (5). The limit line shown in each group of tables define the depth/time limits of the EL-MK 15/16 DCM. The depth and bottom time increments which were used to construct the tables were those felt to be the most useful operationally. Since the tables are computed using the EL-MK 15/16 DCA, tables for any depth and bottom time combinations could be computed if that were desirable.

## Table Safety:

The tables shown in Appendix G should prove safe for even un-worked up divers and are the ones being recommended for Fleet use. The overall raw incidence of DCS for all HeO2 dives using all HVAL's in this study was 3.79% which was almost half of the raw incidence for all schedules tested using a  $N_2O_2$  breathing medium (4), and which is similar to the 3.5% expected incidence for  $N_2O_2$  Tables falling within the final model limits (4). Since all tables computed using HVAL21 are longer than HVAL13 Tables, one could justifiably add the 1135 man dives and 36 cases of DCS from dives falling within HVAL13 limits (Table 6a) to all of the 109 man dives and 3 cases of DCS done during Phase V HeO2 decompression schedule testing to get an overall estimate of 4.0% for the expected incidence on HVAL21 Tables assuming a binomial distribution at the 95% confidence level. Thus, even with only these minimal selection criteria, the HVAL21 Tables have established approximately the same safety record after testing as had the previously tested N202 Tables (4).

While testing of HVAL21 itself comprised only 109 man dives in Phase V, further testing would not have been beneficial because once the divers became worked up then the shorter HVAL13 Tables would have proven safe. Kather, the true safety of HVAL21 Tables is attested to by 29 DCS free dives at a depth/time combination known to produce a high DCS incidence on fresh divers using HVAL13. The no-decompression limits have been reduced to approximate those of the MK 6  $\rm HeO_2$  schedules which have proved remarkably safe in Fleet use, and the decompression times have been increased substantially over the HVAL13 schedules. Comparison of the 0.7 ATA profiles with the MK 6 SCUBA profiles is difficult but the 60/170 schedule on HVAL21 is 6 min longer than

the corresponding MK 6 schedule and the 80 FSW for 90 min HVAL21 schedule is just 2 min shorter than the MK 6 schedule. Considering the much higher  $PO_2$  breathing 0.7 ATA  $PO_2$  during decompression compared to a 25%  $HeO_2$  mix, these HVAL21 Tables should prove much safer than the current Helium-Oxygen SCUBA Decompression Tables currently being used by the Fleet.

Once divers have become worked up they could dive the HVAL13 Tables. It would appear that 4 no-decompression dives over a 5 day period would be sufficient to work up divers. However, until considerable Fleet experience is gained with HVAL21 Tables and this work up phenomenon is better quantitated through testing, HVAL13 Tables are not recommended for Fleet use.

The high proportion of DCS in this HeO2 series which were Type 2 has led to a very conservative approach in developing operational tables. increase in decompression time in HVAL21 Tables over HVAL13 Tables is one manifestation of that approach. Another is the way diving will be done in the Instead of using 100% He as a diluent gas as was done in these dives, an HeO2 mix will be used. Since additional oxygen will be added to the breathing loop during descent the initial PO2 in the UBA will be well above the 0.75 ATA mean observed in this study during the first several minutes on the bottom. Also, when the MK 16 was designed, it had a set point of 0.7 ATA with a low 02 alarm at 0.4 ATA. Since testing of these profiles was done on a MK 15 which has a low 02 alarm at 0.6 ATA, the low 02 alarm on the MK 16 had to be raised to that level. In doing this the set point had to be raised to So when diving these tables with the MK 16 UBA, an additional 0.75 ATA. degree of safety is introduced.

The emergency procedure using air was successful enough during testing that it too is recommended for Fleet use. This means that in the event of a UBA failure during decompression, the diver can switch to air breathing at any point in the decompression profile and continue to follow the appropriate HVAT'l Table to the surface. After using this procedure the diver should be observed but does not have to be treated unless signs of DCS arise. This emergency procedure was used during the open sea dives described below on a 300 FSW dive without incident. Also, Phase II testing (Profile 30D) has shown that the 10 FSW stop can be taken at 20 FSW or any depth between 10 FSW and 20 FSW if desired. For metric tables the 3 MSW stop can be taken at 6 MSW or any depth in between.

No repetitive diving was done during these dive series and testing of the EL-MK 15/16 DCM on repetitive dives will be necessary before repetitive diving tables can be calculated. This testing will be necessary before the EL-MK 15/16 DCM could be used in an Underwater Decompression Computer for multiple level and repetitive diving. At present, the EL-MK 15/16 DCM using HVAL21 is most useful in computing single depth dive tables.

#### Rules For Using Tables:

The rules for using the decompression tables given in Appendix G were formulated based on the present testing and previous  $N_2O_2$  testing (3,4). While primarily designed for use with the MK 15 or Mk 16 UBA, the tables can be used with any electronically controlled constant  $PO_2$  UBA with a set point

of 0.7 ATA or higher. However, in order to be consistent with the methods used in testing these tables, the UBA should warn the diver if the PO2 falls to 0.6 ATA and the diver should take action to raise the PO2 back to 0.7 ATA at that point. The limit line concept was used so that schedules could be dove right to the limits of the tested depth/time domain and there would be sufficient back up schedules for emergencies or other unforseen circumstances. While no repetitive dive testing was done, rules for considering dives dove within the previous 12 hour period were developed. The choice of a 12 hour "clean dive" time was based on the apparent success of this time in air repetitive diving and in the presumption that helium will offgas at a much faster rate at 1 ATA breathing air than will nitrogen. In addition, since the no-decompression limits for these tables are longer than the air limits and since breathing helium seems to keep decompression time about the same or less than when breathing  $N_2O_2$  (4), it seemed reasonable to be able to compute a residual nitrogen time for use with subsequent air tables using the maximum depth ever attained and the sums of all bottom times for all dives done within the past 12 hours. These rules are felt to be very conservative but are the best that can be developed without the necessity for further man-testing. These rules were developed to give the necessary flexibility for using these tables in the operational environment and will be changed as experience is gained.

HVAL 21 Tables, as shown in Appendix G, were dove on 13 man dives in the open sea from a 19' inflatable rubber boat during testing of MK 16 deployment procedures. Depths of the dives were from 180 FSW to 300 FSW and no symptoms of DCS were noted despite seas ranging 16-18 FSW wave height and water temperatures down to 37°F (20).

#### Relevance To Saturation Decompression:

As a final point, the EL-MK 15/16 DCM using HVAL21 needs to be discussed in the context of  ${\rm HeO}_2$  saturation diving. As discussed earlier, consideration was given to the  ${\rm HeO}_2$  decompression rates and upward excursion limits in determining the 120 min MPTTs and the rate at which these MPTT values are increased with increasing depth. When MPTTs were increased 10 FSW for each 10 FSW of depth increase and an SDR of 1.0 was used the mean offgassing rate breathing a 0.4 ATA (13.2 FSW) PO<sub>2</sub> was:

$$dP/dT = K \cdot (2.8-P0_2) = [ln(2)/l20] \cdot (2.8 - 13.2) = -0.0601 FSW/min$$
or

$$dP/dT = -3.61 FSW/Hr$$

HVAL21 calls for losing 11 FSW of inert gas to ascend 10 FSW and in addition has an SDR of 0.83 for the 120 min tissue giving a mean offgassing rate of:

$$(10/11) \cdot (0.83) \cdot (-3.60) = -2.72 \text{ FSW/hr}$$

This appears slower than presumably safe saturation decompression rates so HVAL21 will predict extremely conservative saturation decompression rates. The surfacing MPTT for the 120 min tissue is 48 FSW and at a  $PO_2$  of 0.4 ATA

this represents saturation at a depth of 28.2 FSW. In reviewing the NEDU diving logs, Duffner, et.al. (17) found that Van Der Aue exposed 6 divers to a depth of 33 FSW on  ${\rm He0}_2$  (assumed to be 20%  ${\rm O}_2$ ) for 36 hours and surfaced them without incidence. At that depth the  ${\rm PO}_2$  is 0.4 ATA so predicting a no-decompression saturation limit of 28.2 FSW appears to be on the conservative side. Reducing the MPTT depth increment increase to 11 FSW per 10 FSW depth increase will also decrease the predicted saturation upward excursion limits. So in the end the reconciliation with  ${\rm HeO}_2$  saturation data had to be compromised in order to obtain a reasonable set of bounce diving tables.

Overall, the most important parameter in  $\text{HeO}_2$  decompression tables appears to be the total decompression time. Stop depth distribution appears important insomuch as shallower stops should be longer than deeper stops but there is no evidence that small variations in stop depth distribution are important. Thus, in further refining the EL-MK 15/16 DCM, retaining total decompression time will be more important than the actual stop depth distribution. It remains to be seen if the EL-MK 15/16 DCM can eventually be modified to compute both bounce and saturation  $\text{HeO}_2$  tables. One major issue remaining to be resolved is how venous oxygen tension varies with changes in arterial oxygen tension. Resolution of this issue is necessary if any decompression model is to be used to compute tables of widely varying inspired oxygen tensions.

#### CONCLUSIONS

- 1. Tables computed with the EL-MK 15/16 DCA using HVAL21 are safe and recommended for operational use.
- 2. HVAL21 Tables can be dove taking the 10 FSW stop at 20 FSW (or 3 MSW stop at 6 MSW for metric tables).
- 3. Air can be breathed during decompression on HVAL21 Tables without table modification.
- 4. The EL-MK 15/16 RTA using HVAL21 cannot be used for multiple level or repetitive diving without further testing.
- 5. A powerful workup phenomenon exists which increases a divers' resistance to DCS as he continues to dive.
- 6. A diver can get worked up by diving 4 no-decompression HeO<sub>2</sub> profiles over a 5 day period.
- 7. A diver will stay worked up over a 4 day period without diving but will lose his increased resistance to DCS some time between 5 and 10 days.
- 8. Further investigation and quantitation of the workup phenomenon observed during this study is necessary before it can be used operationally.
- 9. Tables computed by the EL-MK 15/16 RTA using HVAL13 can only be safely dove by worked up divers.

- 10. The overall incidence of DCS diving constant 0.7 ATA PO<sub>2</sub> decompression schedules using  ${\rm HeO}_2$  was less than diving  ${\rm N}_2{\rm O}_2$  but a higher proportion of DCS breathing  ${\rm HeO}_2$  is Type 2.
- 11. There is a wide individual variation in susceptibility to DCS and severe symptoms may occur even on apparently low decompression stress dives.
- 12. Further modification of the MK 15/16 DCM is necessary before it can be used to compute tables with wide variations in inspired  $PO_2$  and nitrogen levels.

## DIVER PHYSICAL CHARACTERISTICS (Cont.)

Note 1: Body fat percentage computed from triceps (TRI), subscapular (SS), and supra-iliac (SI) skinfolds according to the method of;
Durnin, J.V.G.A., and J. Womersley, Body Fat Assessed from Total Body Density and Its Estimation from Skinfold Thickness: Measurements on 481 Men and Women Aged from 16 to 72 Years. British Journal of Nutrition 32:77-97, 1974.

## APPENDIX B

HANDLING NITROGEN IN
THE MK 15/16 DCM WITH
A HELIUM DILUENT

#### APPENDIX B

#### HANDLING NITROGEN IN THE MK 15/16 DCM WITH A HELIUM DILUENT

EL-MK 15/16 Decompression Model (DCM) assumes that all inert gas in a given compartment exchanges at the same rate, that is it is a single inert gas model. In doing surface oriented  $HeO_2$  diving the diver will initially be saturated with nitrogen and will also have a lung full of nitrogen. When he goes on the fixed PO2 UBA, the total inert gas tension will not exceed 0.3 ATA (since the PO2 is controlled to 0.7 ATA) and of this a certain fraction will be nitrogen and the rest helium. The nitrogen in the UBA will always have a lower partial pressure than that initially in the tissues and the diver will offgas nitrogen throughout the dive and eventually reach an equilibrium where the nitrogen partial pressure in the UBA breathing loop and body is the same and no further nitrogen exchange takes place. In developing the 0.7 ATA fixed PO2 in He MPTT tables, they were adjusted to produce safe decompression schedules under the conditions tested which included a lung full of nitrogen (all divers were in fact instructed to inhale to the end of a normal inspiration before going on the UBA). The adjustment to the MPTT values presumably compensated for any nitrogen present in the body and the final set of MPTT's actually reflect total inert gas tension some of which is nitrogen. But, while the EL-MK 15/16 DCM described here works for closed-circuit UBA's using an HeO2 diluent it might not work for trimix diving or diving where switches between helium and nitrogen inert gas is made. What follows is a brief discussion of the considerations which must be made when extrapolating this model to other conditions.

#### Gas Uptake

When dealing with more than one inert gas the following equation describes exponential uptake:

(1) 
$$P_{IN} = P_{N_2} + P_{He}$$

$$= P_{A_{He}} - (P_{A_{He}} - P_{I_{He}}) \cdot e^{-K_1 \cdot T} + P_{A_{N_2}} - (P_{A_{N_2}} - P_{I_{N_2}}) \cdot e^{-K_2 \cdot T}$$

where:

P<sub>IN</sub> = total inert gas tension

 $P_{N_2}$ ,  $P_{He}$  = tissue nitrogen and helium tension

 $P_{A_{N_2}}$ ,  $P_{A_{He}}$  = arterial nitrogen and helium tension

 $P_{I_{N_2}}$ ,  $P_{I_{He}}$  = initial tissue tension

 $K_1$  = helium time constant

 $K_2$  = nitrogen time constant

Note that the sum  $P_{N_2}$  +  $P_{He}$  is the total inert gas tension,  $P_{IN}$ , which is what the EL-MK 15/16 RTA computes every 2 seconds. The EL-MK 15/16 DCM basically assumes that all gas other than  $O_2$ ,  $CO_2$  and water vapor is a single inert gas with tension  $P_{IN}$ . This is eqivalent to saying that  $K_1$ = $K_2$  and if this is done, equation (1) becomes:

(2) 
$$P'_{IN} = P_{A_{N_2}} + P_{A_{N_2}} - [(P_{A_{He}} + P_{A_{N_2}}) - (P_{I_{He}} + P_{I_{N_2}})] \cdot e^{-K_1 \cdot T}$$

and since,  $P_{A_{He}} + P_{A_{N_2}} = P_{A_{IN}}$  and  $P_{I_{He}} + P_{I_{N_2}} = P_{I_{IN}}$ , then:

(3) 
$$P_{IN} = P_{A_{IN}} - (P_{A_{IN}} - P_{I_{IN}}) \cdot e^{-K_1 \cdot T}$$

which is the gas exchange equation used by the EL-MK 15/16 DCM.

If  $K_1$  is not equal to  $K_2$  then there will be an error in computing total inert gas tension, the magnitude of which is found by subtracting equation (1) from equation (2):

$$E = P_{IN} - P_{IN} = (P_{A_{N_2}} - P_{I_{N_2}})(e^{-K_2 \cdot T} - e^{-K_1 \cdot T})$$

OR

(4) 
$$E = C \left( e^{-K_2 \cdot T} - e^{-K_1 \cdot T} \right)$$

Since this error is time dependent, its value will go through a maximum. At T=0 and when T is very large, E will be 0. To find the maximum, equation (4) is differentiated and the time at which the derivative of zero is found:

$$dE/dT = C[-K_2 \cdot e^{-K_2 \cdot T} + K_1 \cdot e^{-K_1 \cdot T}] = 0$$

OR

(5) 
$$K_1/K_2 = (e^{-K_2 \cdot T})/(e^{-K_1 \cdot T}) = e^{(K_1 - K_2) \cdot T}$$

Now let  $K_1/K_2 = r$ , then equation (5) reduces to:

$$r = e^{(r-1)\cdot K_2 \cdot T}$$

and solving for T:

(6) 
$$T = \ln(r)/[(r-1) \cdot K_2]$$

Substituting this time back into equation (4):

$$E_{\text{max}} = C_{\text{max}} \cdot \left\{ e^{-\left\{\ln(r)/(r-1)\right\}} - e^{-\left\{\left[K_1 \cdot \ln(r)\right]/\left[K_2 \cdot (r-1)\right]\right\}} \right\}$$

or since  $K_1/K_2 = r$ 

(7) 
$$E_{\text{max}} = C_{\text{max}} \cdot \left\{ e^{-\left\{\ln(r)/(r-1)\right\}} - e^{-\left\{\left[r \cdot \ln(r)\right]/(r-1)\right\}} \right\}$$

This equation reduces to:

$$E_{max} = C_{max} \cdot \{e^{\{ln(r)\cdot[-1/(r-1)]\}} - e^{\{ln(r)\cdot[-r/(r-1)]\}}\}$$

OR

(8) 
$$E_{\text{max}} = C_{\text{max}} \cdot \left\{ r^{-[1/(r-1)]} - r^{-[r/(r-1)]} \right\}$$

where: Emax = maximum error

$$C_{\text{max}}$$
 = maximum value of  $(P_{A_{N_2}} - P_{I_{N_2}})$ 

The value of r is the ratio of helium and nitrogen time constants which is the product of blood flow per unit volume times the ratio of blood gas solubility to tissue gas solubility. Values for solubilities of nitrogen and helium taken from Buhlmann (Decompression-Decompression Sickness. Springer-Verlag, New York, 1984) in ml/ml at 1 ATA are:

Gas	Blood	Olive Oil	Blood/Olive Oil Ratio
N2	12.831	66.129	0.194
He	8.886	15.693	0.566

The maxmum value for the ratio of the blood/olive oil ratios for the two gases is 0.566/0.194 or 2.92 which should also be the ratio of  $N_2$  to He halftimes. This value should then be the maximum value for r since the blood flow per unit volume will be he same for each compartment no matter what inert gas is present. In developing his decompression tables, Buhlmann has assumed a value of 2.65 for the ratio of  $N_2$  to He halftimes. The following are values of  $E_{\rm max}$  for various values of r:

r	E <sub>max</sub>
1.00	0
1.5	0.15 · Cmax
2.0	0.25 · C <sub>max</sub>
2.65	0.34°C <sub>max</sub>
2.92	0.38.C <sub>max</sub>

The largest value for  $C_{\max}$  should occur at the beginning of the dive with the body initially saturated with 0.79 ATA of nitrogen and the UBA level around 0.3 ATA (see UBA Oxygen, Carbon Dioxide and Nitrogen Section of main

text) giving a value of  $C_{\text{max}}$  of 0.49 ATA or 16.2 FSW. Assuming a worst case value for r of 0.38, the maximum error estimate would be -6.1 FSW.

#### Gas Elimination

The above analysis is for gas uptake. The situation for offgassing is the same if it is exponential but in the EL-MK 15/16 DCM offgassing is usually linear:

(9) 
$$P = P_I - (P_V - P_A) \cdot .K$$

Using an analysis similar to that above, it can be shown that the error in computing inert gas elimination is:

$$E_{o_{max}} = -(P_{A_{N_2}} - P_{V_{N_2}}) \cdot (K_2 - K_1)$$

OR

(10) 
$$E_{o_{\max}} = -C_{\max}[K_2 \cdot (1-r)]$$

For a given value of r the maximum error will be for the shortest halftime tissue. Values for  $E_{0\max}$  for different halftime tissues and values of r are:

	Eomax									
r	$T_{1/2} = 5 \min$	$T_{1/2} = 120 \text{ min}$								
1	0	0								
1.5	0.07 · Cmax	0.0029°C <sub>max</sub>								
2.0	0.14°C <sub>max</sub>	0.0058°Cmax								
2.65	0.23°C <sub>max</sub>	0.0095 · Cmax								
2.92	0.27 · Cmax	0.0111 · Cmax								

For the faster tissues the maximum error will be about the same as the error made during gas uptake, but for slower tissues the error will be one third of that for gas uptake.

Since nitrogen is always offgassing,  $C_{max}$  is negative and the value for  $E_{max}$  and  $E_{O_{max}}$  will always be negative, meaning that the single gas model will underestimate the total inert gas tension compared to a double inert gas model. As time goes on the difference between  $P_{A_{N_2}}$  and  $P_{I_{N_2}}$  will decrease and the errors will get smaller.

Since the EL-MK 15/16 DCM was tested with divers initially saturated on air, the tissue halftimes and MPTT values are not really pure helium values but are He/N<sub>2</sub> values. If the HeO<sub>2</sub> version of the EL-MK 15/16 RTA is used for other than closed-circuit diving, as described in this report, then extrapolation of the present single inert gas model may not work. Taking into account the above considerations a more rigorous double inert gas model will have to be constructed if repetitive diving breathing air during 1 ATA surface intervals is to be addressed.

#### DECOMPRESSION SICKNESS DESCRIPTIONS

#### PHASE I AND PHASE II NO-DECOMPRESSION DIVES

Table 3 Key	Diver	Date Mod	Profile FSW/Min	DCS Type and Location	Onset Time Post Dive	Comments
•	38	1/21/82 HVAL01	160/11	(1) L. shoulder.	5 min	Complete relief at 47 FSW on compression, Treatment Table 5.
b	29	1/23/82 HVAL02	100/41	(2) Nausea, generalized weakness, skin mottling, pain L. Scapula.	l min	Complete relief after 10 min at 60 FSW, Treatment Table 6.
	40			(1) L. shoulder.	2 min	Complete relief after 20 min at 60 FSW, Treatment Table 6. (Treatment Table 6 ex- tended one O <sub>2</sub> period at 60 FSW to accom- modate diver #9 Treatment Table 5 below.)
	9			(1) L. ahoulder.	60 min	Complete relief upon arrival at 60 FSW, Treatment Table 5.
c	17	1/25/82 HVAL02	100/41	(1) L. ahoulder.	1 min	Complete relief at 45 FSW on compression, Treatment Table 5.
	18			(1) Sterno-clavicular joint.	l min	Complete relief at 30 FSW on compression, Treatment Table 5.
d	38	1/25/82 HVAL02	140/15	(1) Hips, costo-vertebral joints, costo-chondral junctions.	4 min	Hip pain gone by 5 min at 60 FSW. All other symptoms gone upon arrival at 60 FSW. Treatment Table 5.
e	40	1/27/82 HVAL03	100/35	(1) Bilat. severe hip pain.	5 min	Complete relief at 30 FSW on compression, Treatment Table 5.
f	38	2/1/82 HVAL03	120/25	(1) L. shoulder, ribs.	l min	Complete relief by 6 min at 60 FSW, Treatment Table 5. Repeat treatment for residual soreness 1 hrs later with no changes at 60 FSW. Kesidual soreness not considered DCS.
	8			(1) Low back pain L4/L5 inter-vetebral joints, no radiation.	8 min	Previous history of low back pain. Had mile low back pain on previous dive which was untreated but resolved. This pain in same area but more intense. Complete relief at 40 FSW on compression, Treatment Table 5.
	35			(1) L. scapula, rhomboid, deltoid, and costochondral region (pains nonradiating). (2) Leg weakness, paresthesias, and inability to urinate.	5 min 5 hrs	Had been lifting weights day before dive resulting in some mild pectoralis soreness. Complete relief at 17 FSW on compression, Treatment Table 5. Two hrs post treatment Two hrs post treatment developed leg weakness and paresthesias progressing to inability to urinate. Compressed to 60 FSW

improvement in leg strength over 30 hrs stay. Decompressed in 30 hrs as follows: 60+30 FSW, 3 FSW/hr; 30+10 FSW, 2 FSW/hr; 10+0 FSW, 1 FSW/hr. Upon surfacing on 2/4/82 had residual leg weakness and incomplete bladder emptying on urination. Started on Bethanecol 10 mgm q.i.d. for bladder tone. Over the next week had five Treatment Table 6's at which point treatments were stopped when no further improvement noted after 2 consecutive treatments. Bladder showed only slight residual urine after urination, legs had very mild weakness. Over next week began lifting weights and running. 30 days later, cystometrogram showed normal bladder function. Only mild leg symptoms (weakness and decreased agility) noted with hard physical activity (e.g. touch football). Only objective neurological aigns, very slight decrease in R. wrist and L. foot and toe dorsiflexors when compared to other sides. Completely normal 1 month later. Resumed normal diving activity on air in May 82. Began training for serious running in June. Two years later only subjective problem was 3 min increase in 10K running time to 37 min. Has been air diving since May 82 to 200 FSW without any problems.

	20			(2) Paresthesia R. thigh, tightness of R. hip & knee.	6 hrs	Symptoms developed overnight. Reported next day for treatment Relief after second 02 period. Treatment Table 6.
q	64	4/21 HVAL07	180/45	(1) R. knee.	3 hrs	Complete relief upon arrival at 60 FSW, Treatment Table 5.
	12			(1) R. shoulder.	10 min	Complete reliet upon arrival at 60 FSW, Treatment Table 5.
	56			(1) R. shoulder. L. shoulder, bilat. hip.	70' Stop	Diver pulled K. shoulder on bottom producing sharp pain lasting few min. Pain noticeable at 70 FSW stop. Very noticeable at 10 FSW stop. Uther symptoms occurred after surfacing. Complete relief on arrival at 60 FSW, Treatment Table 6
	72			(1) Wrist, knee, ankle.	13 hrs	Complete relief after 20 min at 60 FSW, Treatment Table 6.
r	61	4/23 HVAL09	180/45	(1) Bilat. knee. (resolved spontaneously). (1) Recurrence knee pain.	l min 4 hrs	Bilat. knee pain noted post dive but re- solved. 4 hrs post dive went running with recurrence of knee ache. 5 hrs post dive knee ache increased and got worse again with hot shower. Complete relief upon arrival at 60 rSw, Treatment Table 5.
•	59	4/27 HVAL09	150/30	(1) R. shoulder.	10 min	Complete relief upon arrival at 60 FSW, Treatment Table 5.
t	40	4/28 HVAL09	120/40	(2) R. shoulder pain.  Bilat. hip and upper extremity weakness.	10' Stop	Shoulder symptoms noted 2 min before leaving 60 FSW stop. Completed 120/40 schedule before surfacing. Other symptoms developed after surfacing. Complete neuro exam after compression to 60 FSW normal.
•	min of	sympto	m onset	R. sided weakness, nausea, vomiting, loss taste on ant. tongue, intercostal and diaphragm weakness, L. side decreased sensation to light touch and pinprick.		Felt fatigued throughout treatment. Complete relief upon arrival at 60 FSW, Treatment Table 6.  After completing Treatment Table 6, diver left chamber and appeared normal. During post treatment physical became nauseated and vomited. Rapid onset of R. sided weakness ensued. Noted change in taste of ant. 2/3 tongue (postulated mid brain lesion). Compressed to 60 FSW within 10 36 hrs, decompressed in 30 hrs as follows:

min of symptom onset with slight improvement. Kept at 60 FSW 36 hrs, decompressed in 30 hrs as follows: 60+30 FSW, 3 FSW/hr; 30+10 FSW, 2 FSW/hr; 10+0 FSW, 1 FSW/hr. Strength improved at 60 FSW with 02 breathing. 02 stopped because of severe insp. pain (02 tox.). Surfaced on 2 May with R. arm and leg weakness, decreased spotty R. sided light touch and pinprick deficits, decreased taste sensation ant. 2/3 tongue, PFT's decreased to 33-50% normal. Pain of 02 tox. prevented further treatment till 2 wks later. Static lung pressure measuements showed decreased (50% normal) insp. and exp. max. pressures. Most of PFT decrease probably due to intercostal muscle and diaphragm weakness. Next week received a total of 5 treatments (3-4 hrs) at 30-40 FSW on 100% 02. Would not tolerate 02 deeper than 40 FSW. Some improvement in strength and paresthesias. Treatment stopped because no further improvement noted on last 2 treatments. Three weeks later had decreased strength only noted in running and athletic activities, dyspnea sfter running 1/2 mile and on immersion. Regained full function by Dec 82 with no further treatments. Disqualified fy a diving but continues sport diving without problems.

TABLE C-3
DECOMPRESSION SICKNESS DESCRIPTIONS

#### PHASE 111 DECOMPRESSION DIVES

	Diver	A 27 C	Profile		Onset Time	
Key	*	Mod	FSW/Min	DCS Type and Location	Post Dive	Comments
u	98	8/5/82 HVAL11	120/40	(2) Nausea, vomiting, L. knee pain.	2 hrs	Complete relief on arrival at 60 FSW, Treatment Table 6.
	100			(1) R. knee.	2 hrs	Complete relief on arrival at 60 FSW. Treated on Table 6 with above diver (#98).
	90			(1) R. knee.	1 hr	Complete relief on arrival at 60 FSW, Treatment Table 5.
	102			(1) R. shoulder.	2 hrs	Complete relief at 10 min at 60 FSW, Treatment Table 5.
V	85	8/16/82 HVAL11	100/90	(1) Bilat knee.	1 min	Symptoms initially present on surfacing. L. knee resolved in 1.5 hrs but R. knee pain persisted. Treatment began 1.5 hrs post dive. Complete relief at 53 FSW on compression, Treatment Table 5.
	17			(1) R. knee.	l min	Symptoms reported and treated 1.5 hrs post dive. Complete relief upon arrival at 60 FSW Treatment Table 5.
w	98	8/18/82 HVAL11	60/70	(2) Vertigo, nausea, dia- phoresis.  Decreased hearing, tin- nitus (abnormal audiogram).	80 min	Complete relief after 18 min at.60 FSW, Treatment Table 6. Compression to 60 FSW took 10 min because of trouble equalizing. Complete relief after 12 min at 60 FSW. (Normal audiogram post treatment). Treatment Table 6.
x	103	8/23/82 HVAL11	160/25	(1) L. deltoid muscle at humeral insertion.	l min	Noted slight pain only with movement post dive. Improved with hot shower but increased overnight. Reported 20 hrs post dive for treatment with pain and stiffness in shoulder. Stiffness gone at 60 FSW, pain mild and only in certain positions. Treatment Table 5.
y	97	8/25/82 HVAL11	250/25	(2) Syncope, weakness, fatigue.	50 min	Returned to normal just before treatment started except for fatigue. Neuro on arrival at 60 FSW WNL except for mild mailaise. In retrospect may have been postural hypotension unrelated to decompression sickness. Treatment Table 6.
z	104	9/1/82 HVAL13	300/10	(1) R. shoulder.	15 min	Complete relief upon arrival at 60 FSW, Treatment Table 5.

TABLE C-4

#### DECOMPRESSION SICKNESS DESCRIPTIONS

#### PHASE IV DIVES

Table 7 Key	Diver	Date Mod	Profile FSW/Min		Onset Time Post Dive	Comments
88	111	9/8/83 HVAL13	120/40	(1) L. knee.	6 hrs	Complete relief on arrival at 60 FSW. Treatment Table 5.
	118			(1) Bilat. knee.	12 hrs	Complete relief on arrival at 60 FSW. Treatment Table 5.
	122			(1) L. hand.	90 min	Generalized hand discomfort with flexing. Complete relief after 10 min at 60 FSW. Treatment Table 5.
	123			(2) Generalized weakness, L. leg paresthesia.	8 hrs	Symptoms progressed rapidly over 30 min after first being noticed. Improvement of symptoms after 2 extensions of Treatment Table 6 at 60 FSW. Decided to keep at 60 FSW until symptoms resolved. Complete relief afer 10 hrs at 60 FSW. Decompressed as follows: 60+30, 3 FSW/hr; 30+10 FSW, 2 FSW/hr; 10+0 FSW, 1 FSW/hr.
	128			(2) Ulnar nerve paresthesia, slightly decreased grip strength.	8 hrs	Symptoms began suddenly. Complete relief after 10 min at 60 FSW. Treatment Table 6.
	129			(2) Back tightness, pares- thesias R. lat. forearm, little finger.	9 hrs	Treated 12 hours post dive. Complete relief after 2 min at 60 FSW, Treatment Table 6. Diver did not consider symptoms DCS until he made a 15 FSW pool dive next day and noted lessening of symptoms at which time he reported for treatment.
	137			(1) L. shoulder ache.	10 min	Symptoms very mild and resolved in 10 min leaving very mild residual soreness which subsided in 24 hrs. Not considered DCS initially, DCS in retrospect. Not treated.
bb	71	9/19/83 HVAL13	80/50	(2) Confusion, slurred speech, decreased grip strength.	2 hrs	Only partial relief after 2 hrs at 60 FSW. Compressed to 165 FSW with complete relief- after 10 min. After 2 hrs at 165 FSW decompressed to 60 FSW on Treatment Table 4 schedule. Kept at 60 FSW 12 hrs then decom- pressed as follows: 60+30, 3 FSW; 30+10 FSW, 2 FSW/hr; 10+0 FSW, 1 FSW/hr.
cc	111	9/22/83 HVAL13	100/30	(2) Severe low back pain, girdle pain, leg weak- ness.	5 min	Complete relief upon arrival at 60 FSW, Treatment Table 6.  Residual flank and calf soreness next day. No change after 20 min at 60 FSW, decompressed on Treatment Table 5 but symptom not considered DCS.
dd	128	9/23/83 HVAL13	120/40	(2) Loss of balance, dulled mentation, positive Rhomberg to L.	110 min	For 2 min after onset of Symptoms had to be held erect. After that could walk but not with completely normal gait. Complete relief after 20 min at 60 FSW. Treatment Table 6.
	125			(2) Weakness progressing to nausea and vomiting. R. leg weakness and R. ant. lat. thigh hypoesthesia.		Nausea resolved at 30 FSM during decompression. Remainder of symptoms gone after 3rd $^{\rm O}_{\rm 2}$ period at 60 FSM. Treatment Table 6 with one extension at 60 FSW.
ee	120	9/13/83 HVAL13	80/50	(1) Bilat. knee pain.	15 hrs	Complete relief at 10 min at 60 FSW. Treatment Table 5.
ff	119	9/15/83 HVAL13	120/40	(1) R. knee, L. shoulder.	60 min	Complete relief after 5 min at 60 FSW. Treatment Table 5.

TABLE 0-5

#### DECOMPRESSION SICKNESS DESCRIPTIONS

#### APPENDIX G

### FINAL DECOMPRESSION TABLES (HVAL 21)

Tables in feet with 10 FSW Stop Depth Increment and in meters with 3 MSW Stop Depth Increments

Tables of different depth grouping are separated by a solid line. Within each depth grouping is a limit line. Profiles above the limit line are the only ones used in planning a dive. Profiles below the limit line are for emergency use only. Each profile is backed up by profiles down to 20 FSW (or 6 MSW) deeper and up to 20 minutes longer.

# Rules for Using 0.7 ATA Constant PO<sub>2</sub> in Helium Decompression Tables

- 1. These tables are designed to be used with a MK 15 or MK 16 UBA (or any other constant  $PO_2$  closed circuit UBA) with a setpoint of 0.7 ATA or higher and a helium diluent. The diluent may be 100% helium or any appropriate  $HeO_2$  mixture.
- 2. To minimize the amount of nitrogen in the breathing loop, flush the UBA well with  ${\rm He0}_2$  during set up and exhale completely before going on the UBA.
- 3. Tables are grouped by depth and within each depth group is a limit line. These tables are designed to be dove right up to the limit line. Schedules below the limit line are provided for unforeseen circumstances where a diver might experience an inadvertent downward excursion or for some unforeseen reason overstays his planned bottom time. All schedules below 300 FSW are below the limit line.
- 4. Tables are selected according to maximum depth obtained during the dive and bottom time (time from leaving surface to start of decompression).
- 5. Rules during ascent are the same as for standard air tables.
- 6. When selecting the proper decompression table, all dives done within the past 12 hours must be considered. The following rules apply for the various situations which may occur.
  - a. The last dive was 12 hours or more ago.

Select the table for the maximum depth attained and the total bottom time of the current dive.

b. All dives within the past 12 hours were from these tables.

Add the bottom time of the current dive to the sum of the bottom times for all dives within the past 12 hours to get the adjusted bottom time. Use the maximum depth attained within the past 12 hours and the adjusted bottom time to select the appropriate table.

c. All dives during the past 12 hours were from the Navy Standard Air Tables.

Compute a residual nitrogen time as if the currently planned dive were an air dive. Add this residual nitrogen time to the total bottom time of the currently planned  ${\rm HeO}_2$  dive to get the adjusted total bottom time. Use the maximum depth of the current dive and the adjusted total bottom time to select the appropriate table.

# Rules for Using 0.7 ATA Constant PO<sub>2</sub> in Helium Decompression Tables (Continued)

d. Dives within the past 12 hours consisted of dives from more than one of the various tables in the Diving Manual or from tables other than these or the standard air tables.

Use the procedure in paragraph b. above.

e. If an air dive is planned following using these tables, an air repetitive group for use with future air dives may be computed as follows:

Add the bottom times of all HeO<sub>2</sub> dives done within 12 hours of surfacing from the final dive from these tables to get an adjusted bottom time. Find the air table with the maximum depth attained during the past 12 hours and the adjusted bottom time. The repetitive group from this air table may then be used as the surfacing repetitive group from the last dive. The surface interval credit table is used to find the repetitive group at the end of the current surface interval and the appropriate residual nitrogen time for the current dive.

- 7. The last stop may be taken at 20 FSW if desired. After completing the prescribed 20 FSW stop, remain at any depth between 10 FSW and 20 FSW inclusive for the 10 FSW stop time as noted in the appropriate decompression table.
- 8. In emergency situations (e.g. UBA floodout during decompression) air may be breathed for any part or all of the decompression without modification of the decompression table. If this is done, the diver should be closely observed for signs of decompression sickness for 2 hours following the dive but need not be treated unless symptoms arise.

MK 15/16 0.7 ATA PO<sub>2</sub> in He Decompression Tables

Depth in Feet of Sea Water (FSW) Stops in 10 FSW Increments

NOTE: Time/Date reflects only when tables actually printed, not version.

#### APPENDIX H

#### DIVE PROFILE COMPARISON

All Profiles Assume 60 FSW/min Ascent and Descent Rates.

Times at Depth Are Bottom Time and Include Descent Time From the Suface.

Times Are Either Min or Min: Sec.

Profile Numbers Refer to Table 1 or Table 2.

TABLE H-1

DIVE PROFILE COMPARISON

NO-DECOMPRESSION LIMITS

(Bottom Times in Decimal Minutes)

Depth				HVAL
